be eaſily and cheaply performed. Buſh-harrowing is ſuppoſed of very little-uſe, as it can only ſweep the duſt or light mould over the holes, and in the firſt ſhower of rain that follows, moſt of them will be ſeen, and much of the wheat be ſwelled out of them. In the practice of dibbling peaſe and beans as done in Glouceſterſhire and Middleſex, the method is chiefly this, the work being performed by women: as ſoon as the land can be got properly harrowed, and the ſurface ſmoothed, in the ſpring, that is, in the beginning and middle of February, the work of ſetting commences; in ſome places, in rows acroſs, but more frequently along the ridges. Some ſetters uſe a line to direct them in forming the rows at equal diſtances; others again, particularly thoſe who have been long uſed to the buſineſs, do not conſider the line as neceſſary. The ſetters begin each at the end of a row, and making holes at the diſtance of about two inches from each other, and about the ſame depth, depoſit one pea or bean in every hole, and thus proceed, till the work be compleated. The diſtance between the rows is ſeldom leſs than ten, and in few inſtances, more than fourteen inches. The quantity of ſeed neceſſary is from two and a half to three buſhels, according to the diſtance of the rows; and the price of ſetting, from *3s. 6d.* to *4s. 6d.* the acre. When the ſetting of the field is completed, it is gently harrowed, in order to cover the ſeed, and the crop is repeatedly hand-hoed afterwards, as occaſion requires. If," Mr. Donaldſon obſerves, "the object which the Glouceſterſhire farmers have in view in adopting this practice, be to furniſh employment for the poor, the crops being always repeatedly hand-hoed by the perſons who were employed in putting the ſeed in the ground, is a ſtrong additional circumſtance in ſupport of the juſtneſs of the principles on which it was adopted, and of which thoſe who are in the habit of ſetting wheat cannot avail themſelves. If an extraordinary number of people be not employed, theſe repeated hoeings muſt take up a conſiderable period, and will not, in ordinary caſes, be finiſhed before the commencement of the hay-harveſt; which being again ſucceeded by the corn-harveſt, the induſtrious poor are thus furniſhed with almoſt uninterrupted employment in the fields for ſix or ſeven months. In diſtricts where the poor, from long habits of idleneſs, have become numerous, profligate, and uſeleſs members of ſociety, this muſt be conſidered in every point of view advantageous; while, under other circumſtances, this method of managing bean-crops might be impracticable, from the rate of wages, and the people being fully employed in manufactures; or if practicable, neither beneficial to the community nor to individuals. Where theſe circumſtances occur, and thus fortunately do ſo over the greateſt part of this iſland where improved agriculture is practiſed, drilling beans, or dropping them in the bottom of every ſecond or third furrow, and afterwards horſe-hoeing the crop, will be found a method not leſs favourable for the ſoil: and it at all, but in a ſmall degree, leſs profitable to the farmer. It has been remarked, that it will obviouſly be neceſſary with theſe crops, to have larger ſpaces between the rows, and greater diſtances in them, which muſt render a larger portion of ground capable of being planted in a given time. When the children engaged in performing the work of dropping the ſeed into the holes, are only able to drop into one hole, ſix are required to follow one dibbler; when capable of dropping into two holes, three are ſufficient for one dibbler; and where they can drop into three holes, two are only requiſite for a dibbler. The wages are various, according to theſe circumſtances; for thoſe who perform in the firſt manner, it is generally three-pence a-day for each child; in the ſecond, it is ſeven-pence; and in the third, about ten-pence half-penny. Four men to perform the buſineſs of dibbling, with a ſuitable number of droppers, are conſidered as ſufficient to work in one party, which is a much better practice than that of allowing the whole to work together, as the ſeed is ſet with much greater regularity and exactneſs. The expence of performing the buſineſs is generally about nine or ten ſhillings an acre for wheat, eight for barley and oats, and ſeven for peaſe or vetches; but this muſt evidently be liable to conſiderable variation, according as the ſituation is populous, and the price of labour is cheap, or the contrary. In ſome of the dibbling diſtricts, the difficulty and expence of the hand method have been attempted to be leſſened by the uſe of machinery, ſuch as rollers of the dull, and ſpiked kind. The manual practice is, however, to be preferred, where labourers can be procured. This circumſtance of uſing implements for the purpoſe of putting in the corn, has probably led ſome to ſuppoſe that the practice of dibbling was more on the decline, than is perhaps really the caſe.

It may be obſerved that the kind of ſoils on which this method of putting in the ſeed has been practiſed with the moſt advantage, is the light and mixed ſandy, and thoſe of a loamy quality. On the deep ſtiff clays, it is ſeldom had recourſe to. The newly broken up lands of almoſt all deſcriptions may in ſome caſes be advantageouſly planted in this way. And various ſorts of crops have been found capable, in particular ſituations and circumſtances, of being put into the ground in this way with advantage, ſuch as thoſe of wheat, barley, oats, peaſe, beans, and vetches: the firſt is, however, the kind of crop for which it is moſt commonly employed. Oats may in many caſes be beneficially dibbled on ſuch lands as have been newly ploughed up from leys. But it is ſuppoſed by the author of the Suffolk Report, that barley can ſeldom be dibbled, by reaſon the land is ſo dry in April, that the holes will run in, and not ſtand open to receive the ſeed.

In the more ſouthern parts of the kingdom, the moſt favourable ſeaſon for putting in wheat in this mode has been found to be the latter end of September, or the beginning of October; the months of March and April for barley and oat-crops, and for peaſe and beans as early in the ſpring months as the nature of the ſeaſon will admit of its being done.

With regard to the quantity of ſeed that is required in this method of putting it into the ground, it is conſiderably leſs than where the broad caſt, or perhaps even the drill-ſyſtem is followed; but the ſavings muſt conſtantly depend in a great degree upon the ſteadineſs and accuracy of the perſons employed in dropping the ſeed, and the number of the ſeeds that are put into each hole. It has been ſuggeſted by an experienced cultivator in this way, that where the droppers are properly attended to, the ſaving in wheat may be about ſix pecks in the acre, in barley eight, and in peaſe and vetches about four.

It is ſtated that the number of grains that are depoſited in each hole is different, in different circumſtances, but the moſt general practice, and that which has been found the moſt ſucceſsful, is, three or four for grain-crops, and one or two for thoſe of peaſe, beans, and others of the ſame kind. It is evident, however, it is ſuppoſed, that they ſhould neither be ſet too thickly, nor in too thin a manner; as in the former caſe, the plants may be drawn up, and the crops, in conſequence, become weak and unproductive: and in the latter, as where only one grain is placed in each hole, they may be ſo thin as to afford but a ſcanty produce from the want of plants. Where due care has been taken in the putting in of the ſeed, there is moſtly a conſiderable increaſe of produce in this way of ſowing over the others.

The exact amount of the additional produce that is thus obtained,

obtained, has not, however, been fully ſhewn by the experiments of intelligent cultivators; but it has been ſuppoſed in reſpect to wheat, to be from four to ſix buſhels in the acre, in the Report of Agriculture for Norfolk, and the reſult of an experiment, made with the view of aſcertaining the difference in the produce between ſowing and ſetting barley, proves it to be ſtill greater in that ſort of grain, the experimenter having had twelve buſhels on the acre more in the land that was dibbled, than that which was ſown. Concluſions drawn from looſe eſtimates, or ſingle experiments, ſays the author, cannot, however, be depended upon; but it can ſcarcely be doubted, that the quantity of produce is greater in the method of dibbling the ſeeds, than ſowing it broad-caſt. In the quality of the grain, there is likewiſe a ſuperiority: the wheat and barley produced in this way are ſaid to be not only more free from droſs, but larger in the kernel, and conſequently weighing conſiderably heavier. It is eaſy to perceive, that when the ſeed is put into the ſoil in the regular and equal manner that is the caſe in ſetting with the hand when well performed, the crops, of whatever kind they may be, may have a ſuperiority in theſe different reſpects, both from the plants, in ſuch inſtances, being leſs crowded together, and their becoming, in conſequence, more ſtrong and vigorous, and from the air and ſun being more fully admitted, by which they become more equally, as well as more perfectly, ripened. It is probable too, that in ſuch caſes, from the greater regularity of the plants, the hoeing or after-culture of the crops, where it is practiſed, may be more effectually, and more fully performed. There is alſo another reaſon, that, in particular inſtances, has been ſuggeſted as the cauſe of the quality of the grain in this mode of ſowing being ſuperior; which is that of wheat being frequently dibbled upon ſuch land as has been broken up from a new clover-ley, in which caſe, the ſeeds being ſet in the furrow ſlice, or flag, the plants are not liable to be obſtructed in their growth: whereas, when ſown in the uſual broad-caſt method, much of the ſeed muſt of courſe fall into crevices and openings between the furrow-ſlices, where they muſt be greatly impeded in their vegetation by weeds and other cauſes. This ſhews likewiſe the abſurdity of putting wheat crops in by the broad-caſt method upon ſuch preparations of the land."

In the Norfolk Report on the ſtate of agriculture, ſeveral minutes on this practice are introduced by Mr. Young, by which it would ſeem that there are two methods of performing the buſineſs; thoſe of putting one, and two rows on each flag or furrow-ſlice. About Brandon and Old Buckingham, &c. in that diſtrict one row on an eight inch flag, or even a narrower one, is preferred. At Oxborough, and its vicinity, they put in, of wheat, in this way, ſix pecks to the acre. This they find better than two rows; and to be much ſuperior to drilling. The crops are afterwards well hoed, and generally prove very beneficial. It is ſuggeſted by ſome farmers that this practice ſhould only be had recourſe to while the ſeaſon ſuits, either for wheat or oats, both of which are there dibbled, as when the land is wet and cold, the water is apt to lodge in the holes, and deſtroy the vegetative power of the ſeed.

In many other places in the county, two rows on the flag, often as near as they can be put, are, however, held in preference. In this manner, from ſix to ſeven pecks, but in ſome caſes, nine are put in, to the acre. The work is ſuppoſed by ſome to be beſt performed by women with a proper perſon to ſuperintend them, as they are more obedient and manageable. The expence is uſually from nine ſhillings to ten ſhillings and ſixpence the acre.

It is ſuppoſed by Mr. Everit, that one buſhel of ſeed would be ſufficient. He made an experiment in the view of forming a compariſon of the beſt manner of executing the buſineſs. The uſual mode is, to ſpread the two rows on the flag in ſuch a manner, that they are liable to be too near the ſeams; but he directed the dibblers to keep their hands as cloſe together as they could work them, ſetting the two rows very near each other in the centre of the flag. And the reſult, he ſays, proved the excellence of the practice, the crop having a very beautiful appearance. Mr. Crow is, however, inclined to ſuppoſe a good proportion of ſeed neceſſary, as he has never ſeen a good crop of wheat that was thin; beſides its being more liable to the attacks of the mildew.

The whole of the obſervations would appear to ſhew, that the practice is not to be purſued merely as ſaving ſeed, as was at firſt ſuggeſted; but from the buſineſs being performed in a more advantageous way than by other methods. It is, indeed, remarked by Mr. Johnſon, that it is a practice of ſuch excellence, "that equal crops are not to be gained in any other way;" but that "three grains ſhould always be put in every hole; for, on various examinations, he has found, that a ſingle kernel in a hole, has almoſt always produced a faint ear, ſcarcely ever a good one."

It is probable, from what has already been remarked upon this ſubject, that a ſingle row on a flag may be the moſt proper where hand-weeding is afterwards practiſed; but that where this is neceſſary, two rows on the flag may be a more advantageous method, and that more than one grain ſhould, in general, be put in each hole.

The advantages which have, on the whole, been chiefly looked to in this mode of putting in crops, are thoſe of ſaving ſeed; having the lands, where inclined to be light, ſufficiently trodden; the keeping of the crop clean, rendered leſs difficult; and the employing of a number of women and children, who would otherwiſe be out of work. Beſides, it is ſuppoſed that the crops are not ſo liable to lodge in bad ſeaſons, from their having better hold of the ground, and the ſtraw being more ſtiff, and in reaping the grain being leſs apt to ſhed or drop out of the ear. See DRILL and DRILL-*huſbandry*.

DIBE, or PESCHIERA, in *Geography*, a town of Egypt, on the coaſt of the Mediterranean: 18 miles S.E. of Damietta.

DIBI, a town of Egypt, on the W. ſide of the Nile; 8 miles S.E. of Roſetta.

DIBLATHA, or DIBLATHAIM, in *Ancient Geography*, a town beyond Jordan, at the foot of mount Nebo or Piſgah. Jer. xlviii. 22.

DIBOMA, a town of Macedonia, in the country of the Eordites. Ptolemy.

DIBON, a town of Judea, in the tribe of Gad, given to this tribe by Moſes, and afterwards ſurrendered to Reuben. (Numb. xxii. 3. 33, 34.) Euſebius ſays, that it was a large town on the river Arnon. It was probably the ſame with Dibon-Gad, an encampment of the Hebrews. (Numb. xxxiii. 45.)—Alſo, a town in Judah, the ſame, perhaps, as Debir, or Kirjath-Sepher. Nehem. xi. 25.

DIBRA, in *Geography*, a town of European Turkey, in Macedonia, on the confines of Albania. It was beſieged by the Turks in the year 1442, who, by conveying a dead dog into the only ſpring which ſupplied the town with water, obliged the inhabitants to ſurrender: 30 miles N. of Ackrida.

DIBS, a name given at Aleppo to the inſpiſſated juice of the grape, which has much the appearance, ſays Ruſſel, (vol. i. p. 82.) of coarſe honey, but is of a finer conſiſtence. It is much uſed by the inhabitants of Aleppo; is brought

to town in large goat-ſkins, and retailed in ſmall quantities in the bazars. This is ſuppoſed by Dr. Geddes to be the honey, דבש, mentioned Gen. xliii. 11. Neither common honey nor palm-honey, he ſays, (Crit. Rem. p. 135.) could have been conſidered as a rare gift to a governor of Egypt, where palms and bees were ſo abundant; whereas raiſin-honey, or a ſyrup made out of the grapes, which did not grow in Egypt, might be deemed even a royal preſent.

DICA, in *Law*, a tally for accounts, by the number of tallies, cuts, or notches.

DICACITAS, in *Oratory*, the name given by Cicero (De Oratore, l. ii. c. 54.) to that kind of wit which uſually lies in a ſingle ſentance or word, and which may be termed "conciſe wit or jeſting." The other kind he calls *cavillatio*, which is confined within no certain limits, and which, in our language, may be called "continued wit or humour."

DICÆA, in *Ancient Geography*, a town of Thrace, in the territory of the Biſtonians, and near the Biſtonide Marſh. It was alſo named *Dicæopolis*.—Alſo, a town of Greece, on the Thermaic gulf.—Alſo, an epiſcopal town of Africa, in Bizacium.

DICÆARCHA, a place in Italy, ſo called by the Greeks, and named by the Latins *Puteoli*, which ſee.

DICDICA, a town of Africa Propria, according to the Itinerary of Antonine.

DICE, among *Gameſters*, certain cubical pieces of bone or ivory, marked with dots on each of their faces, from one to ſix, according to the number of their ſides.

Sharpers have ſeveral ways of falſifying dice: 1. by ſticking a hog's briſtle into them, ſo as to make them run high or low as they pleaſe; 2. by drilling and loading them with quickſilver; which trick is diſcovered by holding them gently between two diagonal corners; when, if falſe, the heavy ſide will turn always downwards; 3. by filing them. But all theſe methods fall far ſhort of the arts of the dice-makers, ſome of whom are ſo dextrous, that ſharping gameſters will give any money for ſuch dice. Dice are ſaid to have been invented by Palamedes at the ſiege of Troy, for the amuſement of the officers and ſoldiers.

Dice pay a large ſtamp-duty, and are prohibited to be imported.

Dice *Marle*, in *Huſbandry*. See Marle.

DICEARCHUS, in *Biography*, a follower of Ariſtotle, was a native of Meſſenias, and acquired diſtinction by his philoſophical diſputations, and hiſtorical writings. Cicero (Tuſc. Quæſt. l. i. c. 10.) ſpeaks of him as a learned and eloquent writer. His tenets were that there is no ſuch thing as mind, or ſoul, either in man or beaſt; that the principle, by which animals perceive and act, is equally diffuſed through the body, is inſeparable from it, and expires with it; that the human race always exiſted; that it is impoſſible to foretel future events; and that the knowledge of them would be an infelicity. He was an eminent geographer, and took great pains, to meaſure the height of mountains, and to conſtruct accurate maps of countries. Plin. l. ii. c. 65. Fabr. Bib. Græc. v. ii. p. 295.

DICERA, in *Botany*, (from δις and κερας, alluding to the two horns of the anthers,) a genus of Forſter's, referred by Linnæus the younger to *Elæocarpus*. See Elæocarpus *Dicera*.

DICERATION, in the *Writers of Medicine*, a name given to a collyrium mentioned by Celſus, and thus named from κερας, a *horn*, burnt hartſhorn being a principle ingredient in it.

DICHONDRA, in *Botany*, (from δις, and χονδρος, *a grain*, on account of the form of the capſule, reſembling two grains or berries.) Forſt. Gen. Pl. 20. t. 20. Schreb. 176. Swartz. Prod. 54. Willd. Sp. Pl. v. 1. 1353. Juſſ. 129. Claſs and Order, *Pentandria Digynia*. Nat. Ord. *Convolvuli*, to which it is now removed by Juſſieu himſelf from his *Borragineæ*, where he had firſt placed it.

Gen. Ch. *Cal.* Perianth inferior, in five deep, regular, obovate, many-ribbed, ſomewhat ſpreading ſegments. *Cor.* of one petal, wheel-ſhaped, regular, in five deep lanceolate ſegments, as long as the calyx; with a very ſhort tube. *Stam.* Filaments five, awl-ſhaped, equal, ſhorter than the corolla, and inſerted into its tube; anthers ovate, blunt, of two lobes. *Piſt.* Germen ſuperior, double, hairy; ſtyles two, as long as the ſtamens, awl-ſhaped, divaricated, originating, according to Forſter, from the inner ſide of each germen at the baſe; ſtigmas capitate. *Peric.* Capſules two, accompanied by the permanent enlarged calyx, each nearly globoſe, of one cell. *Seeds* ſolitary, globoſe.

Eſſ. Ch. Calyx in five deep ſegments. Corolla inferior, wheel ſhaped, in five deep ſegments. Capſules two. Seeds ſolitary. D. *repens* of Forſter, Smith Plant. Ic. t. 8. (Sibthorpia evolvulacea; Linn. Supp. 228.) is eſteemed by Dr. Smith the only ſpecies. It was ſent by Mutis to Linnæus from New Granada, and was found by Commerſon at Buenos Ayres, and the iſland of Mauritius. It is alſo known to grow in Jamaica, Peru, and New Zealand. The ſtems are proſtrate, creeping, ſlender, branched, round, and leafy. Leaves alternate, on long ſilky ſtalks, upright, kidney-ſhaped, more or leſs emarginate, entire; ſmooth, or ſlightly hairy above; more or leſs ſilky beneath, and marked with radiating ribs. Flower-ſtalks axillary, moſtly ſolitary, ſimple, ſilky, ſhorter than the leaves. Flowers very ſmall, a little drooping, white. Calyx externally hairy, internally ſmooth. Fruit much larger than the flowers. When very ſilky and ſilvery in the aſpect of its leaves, it is the D. *ſericea* of Swartz., Willd. Sp. Pl. v. 1. 1353; but there ſeems to be no permanent ſpecific diſtinction. Poſſibly, if the ſuppoſed varieties were compared in a living ſtate, ſome certain marks of diſcrimination might be obſerved, but no botaniſt has yet had ſuch an opportunity. The Jamaica variety only has hitherto been brought into the more curious gardens of Europe. According to Mr. Donn, it was introduced here in 1786, and is perennial, flowering in the ſtove in July.

DICHORÆUS, in *Poetry*, the foot of a Latin verſe conſiſting of four ſyllables; of which the firſt is long, the next ſhort, the third long, and the laſt ſhort. It is a double *choræus*, as *cōmprŏbārĕ*.

DICHOTOMOUS, in *Botany*, is applied to a ſtem regularly and repeatedly cloven, or forked; more eſpecially if, as uſually happens, a ſolitary flower ſprings from each fork or divarication. Inſtances are found in the genus *Ceraſtium*, and many of its allies, and in *Chlora perfoliata*, Engl. Bot. t. 60. Some leaves are formed in a dichotomous manner, as thoſe of *Ceratophyllum*, and of a ſpecies of Sun-dew from New Holland, thence denominated *Droſera dichotoma*.

DICHOTOMY, *biſection*, a term uſed by aſtronomers for that phaſis, or appearance of the moon, wherein ſhe is biſected, or ſhews juſt half her diſk, or circle; or when ſhe is in the beginning of her firſt and laſt quarter.

The word is Greek, formed of διχοτομεω, *I biſect*, or *cut into two*; of δις, *twice*, and τεμνω, *I cut*.

The time of the moon's dichotomy is of conſiderable uſe in fixing the ſun's diſtance from the earth: and it was anciently applied by Ariſtarchus for this purpoſe. In order to underſtand his method of doing this, we have only to conſider that the phaſes of the moon are produced by the different poſitions of its illuminated hemiſphere with regard

to an obſerver on the earth. Conſequently, when one of theſe poſitions is ſuch that the plane of the circle which ſeparates the enlightened from the dark part, paſſes through the eye of the ſpectator, then the confines of the light and ſhade on its diameter will form a right line: at this time we may ſuppoſe three right lines, *viz.* one drawn from the eye of the ſpectator at T, (*Plate* IX. *Aſtronomy, fig.* 67.) to the centre of the moon, L, another from this centre to that of the ſun S, and a third from the centre of the ſun to the obſerver's eye, at T, to form a triangle T L S, having a right angle at the centre of the moon, a very acute angle at the ſun, and the third approaching to a right angle at T. Ariſtarchus propoſed to obſerve the inſtant that the moon appears dichotomized, and at the ſame inſtant to obſerve the magnitude of the arc intercepted between the ſun and moon, whence he obtained the angle L T S, and thus he found the proportion of the ſides of the triangle, one of which is the diſtance of the moon from the earth, and another that of the ſun; ſo that he hence obtained the proportion of one of theſe diſtances to the other. Ariſtarchus found that this angle was not leſs than 87°, and hence concluded that the diſtance of the ſun from the earth was from 18 to 20 times that of the diſtance of the moon from the earth. He found alſo, by a proceſs of reaſoning, that the diameter of the moon was to that of the earth in proportion greater than that of 43 to 108, and leſs than that of 19 to 60; or ſomewhat leſs than a third of that of the earth. See ARISTARCHUS.

But it is very difficult to fix the preciſe moment when the moon is biſected, or in her true dichotomy. Obſervation informs us, that when ſhe is thirty minutes diſtant from the quadratures, ſhe appears biſected; but ſhe appears ſo too in the quadratures themſelves, and ſome time afterwards, as Ricciolus acknowledges in his Almageſt. So that ſhe appears dichotomized at leaſt for the ſpace of a whole hour: in which time any moment may be taken for the true point of the dichotomy, as well as any other. But the infinite number of moments of time give an infinite diverſity of diſtances. The moment in which the true dichotomy happens being thus uncertain; but it being granted withal, that it happens before the quadrature; Ricciolus takes the middle point between the quadrature, and the time when it is firſt dubious, whether the moon be dichotomized, or not, for the true dichotomy. Keil.

DICHOTOMY, in *Botany*, a term uſed to expreſs that diviſion of the branches, which we ſee in miſletoe, and in the greater part of the ſea-fucuſes, in which each branch is divided into two. See DICHOTOMOUS.

DICHOTOPHYLLUM, the name by which Dillenius, and ſeveral others, call the hydroceratophyllum of Vaillant, and ſome other writers; a genus of plants characterized by Linnæus in his Genera Plantarum under the name of ceratophyllum.

DICHROMENA, (from δι or δις, and χρωμα, *colour*, alluding to the variegation of white and green in its involucrum.) Michaux Fl. Boreal-Amer. v. i. 37. Vahl. Enum. v. 2. 240. Claſs and order, *Triandria Monogynia*. Nat. Ord. *Cyperoideæ*.

Gen. Ch. *Spikelet*, compoſed of ovato-lanceolate concave glumes, imbricated in all directions, and ſeparating the florets. *Cor.* none. *Stam.* Filaments 3, very rarely 1 only, elongated after flowering; anthers linear. *Piſt.* Germen minute; ſtyle capillary, elongated; dilated and compreſſed at the baſe; ſtigmas 2, capillary, the length of the ſtyle. *Peric.* none. *Seed* ſolitary, ſomewhat lenticular, tranſverſely rugged and undulated, crowned with an obtuſe beak originating from the permanent bottom of the ſtyle; and deſtitute of briſtles at its own baſe. *Vahl.*

Eſſ. Ch. Glumes imbricated every way. Corolla none. Stigmas 2. Seed ſomewhat lenticular, tranſverſely rugged and undulated, crowned with a blunt point, and without briſtles at the baſe.

This genus, founded by Michaux and adopted by Vahl, conſiſts of five known ſpecies, one of which is *Schoenus ſtellatus* of Swartz and Lamarck, and another *Scirpus reptans* of Richard. *Actes de la Soc. d' hiſt. nat. de Paris*, v. i. 106. Their common habit is thus deſcribed by Vahl.—"They have the aſpect of *Kyllingiæ*. The culms are ſeveral, without joints, triangular in the upper part, ſtriated, clothed at the lower part with the ſheaths of the leaves, which are numerous, undivided, and very minutely ſtriated, like the leaves themſelves, which are linear. Involucrum widely ſpreading, compoſed of ſeveral leaflets, reſembling the proper leaves, one of which only is ſhorter than the head of flowers, the others gradually longer. Spikelets ſeſſile, forming a head, oblong. Glumes membranous, whitiſh, pellucid, ſomewhat keeled, acute." The ſpecies are all natives of South America, Carolina, or the Weſt Indies.

DICK, in *Agriculture*, a term provincially employed to ſignify the mound or back of a ditch. See FENCE.

DICK-*Hole*, a word ſignifying the hollow excavation or ditch itſelf. See FENCE.

DICK, in *Geography*, a town of America, in the ſtate of South Carolina; 16 miles W. of Queenborough.

DICK's *river*, a river of America, in Kentucky, which is a branch of Kentucky river, joining it in a N. W. direction. It is about 50 miles long, and 45 yards wide at the mouth. It has upon it a number of excellent mill-ſeats, and runs through a tract of valuable land.

DICKER, or DICRE, *Dicra* in our *Old Writers*, a quantity of leather conſiſting of ten hides.

Some derive the word from the Greek δεκα, ten.

We find the word dicra applied to other things beſides leather; thus, "Civitas Glouceſtriæ reddebat xxxvi. dicras ferri;" which is interpreted thirty-ſix dickers of iron, ten bars to the dicre. Gales's Hiſt. Brit. 766. ap. Blount.

DICKINSON, or DICKENSON, EDMUND, in *Biography*, a celebrated Engliſh phyſician and chemiſt, in the 17th century, was born at Appleton, in the county of Berks, in the year 1624. From Eton ſchool he was removed in 1642, to Merton college, Oxford. After taking his degree in arts, he was entered in the medical line in 1649, and admitted to the degrees of bachelor and doctor in phyſic, in the year 1656. In 1655, he publiſhed a work, entitled "Delphi Phœnicizantes," &c. deſigned to prove that the Greeks borrowed the ſtory of the Pythian Apollo, and whatever rendered the oracle of Delphi famous, from the Holy Scriptures, and, particularly, from the book of Joſhua. This work, which diſplayed ſingular ſkill in the Oriental and Greek languages, and a profound knowledge of antiquity, procured for the author a high degree of reputation, both at home and abroad, and, induced Dr. Shelden, afterwards archbiſhop of Canterbury, to perſuade him to take orders, and to devote his talents to the ſervice of religion. But he declined a change of his profeſſion. Anthony Wood has ſuggeſted, that the real author of the above mentioned work was Henry Jacob, a prodigy of learning, but a careleſs man, who ſuffered others to obtain that fame, which belonged to him, by ſurrendering to their uſe his laborious productions. But though the evidence adduced by Wood is ſtrong, it is not ſufficient to determine a point, which muſt impeach the character of Dr. Dickenſon, and evince him to be altogether deſtitute of integrity. He, however, had the reputation of being the author, and derived benefit from the opinion that was entertained, in conſequence of it, of his learning,

lage lands are expoſed in times of rain, is, he ſuppoſes, completely ſuſpended, and the water flows away limpid. While the ground continues covered with a cloſe turf, the root-leaves of the herbage ſpreading over the ſurface, abſorb and digeſt the carbonic acid of the atmoſphere, and perhaps, alſo, earthy particles which probably float continually in the air, as before ſtated. As thoſe leaves are ſmothered and decay, they are perpetually increaſing the ſtock of carbon and vegetable mould. The celebrated Mr. Kirwan, indeed, is, he ſays, of a different opinion. He ſuppoſes, that ground lying in paſture is annually diminiſhing in fertility, though in a leſs degree than that from which a vegetable crop is carried off, becauſe a part is reſtored in the excrements of paſturing animals. But though poor ſoils which are incapable of producing a cloſe turf over their ſurface, gain little by lying at reſt, it is evident, that every ſoil, which either from its natural conformation, or from the improvements made on it by proper culture, has attained a cloſe cover of ſweet herbage, is perpetually gaining. Whenever the temperature is mild, a continual reproduction is taking place; and all the horizontal foliage, which eſcapes the mouths of paſturing animals, falls into decay and accumulates on the ſurface. On breaking up ſuch old paſtures a ſurfaced ſtratum may be obſerved, differing in colour and conformation from that which lies under it, the thickneſs of which is in proportion to the time the ground has lain at reſt. What is here ſtated, is, he thinks, corroborated by the following experiment. Having ſometimes obſerved a kind of turf formed over the hardeſt ſtones in certain ſituations, he collected ſome of it which had grown to more than an inch thick on ſome flat ſtones, lying in a damp place, at the foot of a northerly declivity under ſome trees. It ſeemed to have commenced with the growth of ſome of the ſmaller *muſci* and *algæ*. On this ground the *feſtuca ovina* and *poa glauca* had taken root, and formed a ſtrong turf. After it was dried, he ſubjected a pound of it to combuſtion on an iron ſhovel over a fire till it was reduced to black duſt. The reſidue weighed half an ounce, whereas the greateſt reſidue he ever obtained from a pound of dried peat burnt, was not more than five drams. If ſuch a quantity of mould could thus be accumulated by the graſſes growing on a naked rock, may it not accumulate at leaſt in as great a proportion on the ſoil where the ſucceſſion of growth is incomparably greater?

"It is true, he obſerves, that ſome ſoils by long lying at reſt, condenſe ſo much as to incommode the roots of the graſſes, and on others the moſſes prevail ſo much as to overcome the eſculent herbage, but the fertility of the ſoil is not thereby diminiſhed. Its preſent energy is only ſuſpended, while it is acquiring additional vigour for future exertions. When ſuch land is again employed in tillage, the ſpoils of the turf, together with a great part of what has been conſumed by paſturing animals reſtored in excrements, are turned down and mixed with the ſoil, by which its conformation is improved, and its thickneſs and principle of fertility augmented. Hence the tillage crops are plentiful—the ears large and plump—and the produce of one year equal to two or more on land wearied out by perpetual turning.

"It muſt not be underſtood, by what is here or formerly ſaid, that he means to undervalue the operation of the plough. But, as we are ſtudying in what manner the fertility of the country may be preſerved and improved, and the greateſt quantity of diſpoſable produce obtained at the leaſt poſſible expence, it is neceſſary to examine how all thoſe aids which nature offers may be made to co-operate with the artificial means of agricultural improvement, and not blindly expect from mechanical labour, more than it can poſſibly produce. When barren ſoils are to be brought from a wild ſtate, it is by mechanical labours only that their obſtinacy can be ſubdued, and the different ingredients properly blended. The turf of old graſs ground will frequently require a good deal of mechanical operation to mix it with the earths, and facilitate its putrefaction. But when theſe, and ſuch other aids as mechanical labour is adapted to accompliſh, are obtained, that medium of conſiſtence on which fertility depends will be beſt preſerved by alternate ſucceſſions of labour and reſt. The proportion and order of thoſe ſucceſſions muſt no doubt vary greatly according to circumſtances. While thoſe where the ſoil is deep and of the moſt favourable conſtruction, and where adventitious manure is attainable, may be much occupied in tillage crops, without ſuffering great deterioration; in the more elevated grounds, where the ſoil is generally leſs happily conſtructed, expoſed to ſeverer waſhings and manure leſs abundant, a greater proportion of the farm ought always to be in paſture. But in all ſituations and circumſtances, the ſoil will be benefited by being occaſionally at reſt, provided care has been taken to lay it down unexhauſted, free of weeds, and well ſtocked with proper graſſes. By this ſyſtem of alternations of tillage and graſs crops, the attention of the huſbandman is leſs diſſipated, and his labours more regularly diſtributed. The live ſtock fed on his paſture, furniſh him with manure to enrich his tillage fields, and the more they are enriched, they are the better fitted to yield an abundant return of graſs, when they come in courſe to be laid to reſt. When ground is brought to yield abundance of ſweet graſs it is profitable in paſture, and while it continues ſo is ſtill improving in fertility, and becomes more and more adapted to yield plentiful tillage crops. Thus under good management, the fertility of the country may progreſſively advance, and the diſpoſable quantity of proviſions for the uſe of the conſumer, and the net return to the huſbandman, perhaps, exceed what the operoſe and expenſive ſyſtem of perpetual fallowing, and crops without reſt, could produce.

"Convertible huſbandry is not leſs ſuperior to perpetual graſs. Land which lies perpetually in graſs, is deprived of the advantage of having the vegetable ſubſtance accumulating on the ſurface from time to time mixed into the ſoil. By the working of moles, ants, and other vermin, by the condenſation of the ſoil, by the prevalence of moſſes and uſeleſs weeds, the turf is deformed and the reproduction of ſweet paſture diminiſhed. Water is frequently detained on the ſurface, and chills the growth of eſculent herbage, and thus the growth becomes more feeble and ſlow. In proportion to the decay of eſculent herbage, plants which are noxious or unprofitable prevail; the paſture becomes gradually leſs, and the fertility of the ſoil is almoſt uſeleſs to the owner and to ſociety, while it remains in that ſtate."

The practice of this huſbandry muſt of courſe in many inſtances be highly profitable to the cultivator. See TILLAGE and GRASS.

CONVEX, bending down on every ſide, as the outſide of a globular body.

CONVEX *freeze*, *leaf*, *lens*, *mirror*, *ſuperficies*. See the ſeveral ſubſtantives.

CONVEXITY, the exterior ſurface of a *convex*, *i. e.* gibbous and globular thing; in oppoſition to *concavity*, or the inner ſurface, when hollow or depreſſed.

The word is of particular import in catoptrics, and dioptrics; where it is applied to *mirrors* and *lenſes*; which ſee. See alſo REFRACTION.

CONVEYANCE, in *Law*, a deed, or inſtrument, by which lands, &c. are *conveyed*, or transferred, by the proprietor, to ſome other perſon. In the diſcuſſion of this ſubject, it is proper to inquire *who* may thus aliene and to *whom*; and then *how* a man may aliene, or the ſeveral modes of

ma. (Polypodium globuliferum ; Lamarck Encycl. v. 5. 554 ; Filix altiſſima et globuligera major ; Plum. Fil. t. 30.) Fronds twice or thrice pinnate, pointed ; leaflets elliptic-oblong, decurrent, obtuſe, pinnatifid, crenate. Fructification in the ſinuſes, globoſe. Veins wavy. Gathered by Thierry in St. Domingo. A very handſome ſpecies, whoſe ſtalks are roughiſh. Pinnæ taper-pointed with a regularly winged ſtalk ; pinnulæ or leaflets alternate, decurrent, three quarters of an inch long and about half as much in breadth, oblong, ſomewhat elliptical, obtuſe, ſharply crenate at the top, deeply pinnatifid, furniſhed with zig-zag hairy ribs and veins. Fructifications pale, globoſe, each ſolitary in the ſinuſes of the leaflets. Inner involucrum membranous and almoſt white. This ſeems undetermined by Dr. Swartz, unleſs it be his *apiifolia,* which we have not ſeen. The ſynonym of Plumier, unqueſtionably belonging to our plant, he places among the doubtful ſpecies, accidentally writing *minor* for *major.* D. *ſorbifolia* Fronds bipinnate : leaflets ſeſſile, linear-lanceolate, acutely ſerrulated, tranſverſely veiny. Fructifications numerous, globoſe. Inner involucrum very ſhort. Gathered in the iſland of Honimoa in the Eaſt Indies, in July 1797, by the late Mr. Chriſtopher Smith, to whom the author of the preſent article is indebted for moſt numerous and valuable additions to his herbarium. The preſent fern ſeems entirely non-deſcript. It appears to be four or five feet high, of a ſomewhat glaucous green. Frond alternately bipinnate ; its ſtalks pale and ſmoothiſh beneath, ſingularly hairy above. Pinnæ long and taper-pointed, each compoſed of 60 or more leaflets, which are about an inch long, perfectly ſeſſile but not decurrent, linear-lanceolate, acute, finely and ſharply ſerrated, ſmoothiſh above, minutely punctate beneath, and furniſhed with a hairy rib and numerous parallel veins. Fructifications numerous, in a tolerably regular marginal ſeries, ſmall ; their outer involucrum green, cup-ſhaped, crenate, rugoſe when dry, cloſely inflexed ; the inner ſo ſhort as to be not diſcernible till the ball of capſules is removed. D. *glauca.* Fronds bipinnate : leaflets ſeſſile, crowded, oblong, falcate, crenate, glaucous beneath. Fructifications numerous, globoſe. Involucrums equal, entire. Of the height of this fern we know nothing, being poſſeſſed of only a portion of the middle part of its frond, brought by Mr. Menzies from the Sandwich iſlands. The pinnæ are numerous, crowded, a ſpan long, ſmooth, linear-lanceolate, compoſed of very numerous, crowded, ſeſſile, linear-oblong, falcate, convex, obtuſe, crenate leaflets, which are veiny, and very glaucous beneath, each being half an inch, or rather more, in length. The veins are branched and ſmooth. Fructifications in an uninterrupted ſeries on the lower part of each leaflet, at each margin, pale brown when ripe. Outer involucrum truly originating from the margin of the leaflet, though different in texture and colour, concave, kidney-ſhaped, ſmooth and quite entire, embracing the inner involucrum, which is exactly like it, only ſomewhat longer and narrower. We have thought it more uſeful to deſcribe theſe three new ſpecies than to copy the definitions of the remaining 10 in Swartz, among which are *Polypodium nudum* and *Trichomanes flaccidum* of Forſter, *Cænopteris japonica* of Wildenow ; *Polypodium marginale* and *Trichomanes ſtrigoſum* of Thunberg, Fl. Jap. with *Davallia linearis* of Cavanilles, and *repens* and *abrupta* of M. Bory de St. Vincent ; the three laſt equally unknown to Dr. Swartz and to ourſelves, except from deſcriptions. S.

DICKVEL, in *Geography*, a town of the iſland of Ceylon, near the South coaſt ; 102 miles S. of Candy.

DICKWASSET, or DIGDEGUASH, a river of America, in the province of New Brunſwick, which diſcharges itſelf into Paſſamaquoddy bay.

DICLINIA, in *Botany*, (from δις, *double*, and κλινη, *a bed,*) is uſed by Linnæus in his *Syſtema Vegetabilium*, p. 21, for ſuch claſſes or genera of plants as have ſeparated flowers, the ſtamens being in one bloſſom, the piſtils in another. This ſeparation is either complete, as in the claſſes *Monoecia* and *Dioecia* ; or incomplete, as in *Polygamia* ; ſome flowers of the latter claſs having the ſtamens and piſtils together, while in others they are ſeparate. The writer of the preſent article has firſt ſuggeſted, that ſuch ſeparation of the eſſential organs of impregnation in flowers, is of material importance or convenience, either in natural, or even artificial, claſſification, only when it is accompanied by a concomitant difference in the other parts of the flower, as in the Oak, Walnut, Hazelnut, &c. In theſe and ſimilar inſtances the two organs are not liable to meet in the ſame flower. By attention to this circumſtance, the Linnæan claſs *Polygamia*, the burthen and opprobrium of the ſexual ſyſtem, on account of the uncertainties and difficulties which attend its determination, among the trees of tropical climates more eſpecially, will be brought into very narrow limits. If the ſame rule be extended to the claſſes *Monoecia* and *Dioecia*, they will alſo be delivered from numerous genera and ſpecies, whoſe allies or whoſe congeners are in other parts of the ſyſtem. Hence the whole arrangement will become more natural, as well as more eaſy and certain, and the three claſſes in queſtion will be ſo much diminiſhed, that it may be expedient to unite them into one, under the title of *Diclinia.* See Itroduction to Botany, 395, 470, 485, &c. S.

DICOCCUS, FRUCTUS, a two grained fruit or ſeed-veſſel, technically applied to that particular kind of capſule which has the appearance of being compoſed of two roundiſh combined capſules, as in the genus *Dichondra,* ſo named from that very circumſtance. A three-grained, or tricoccous, capſule is much more frequent ; and a whole natural order of plants, to which the *Euphorbia* belongs, derives its character and name from having ſuch a fruit. See TRICOCCÆ.

DICOTYLEDONES, (from δις, *double,* and κοτυληδων, a *cotyledon ;* which laſt word is technically applied to the ſeminal leaf of a plant, apparently becauſe its roundiſh form and fleſhy texture reſembles the herb *Cotyledon* or Navelwort,) is a term uſed for all ſuch plants as have two cotyledons or ſeed-lobes. See COTYLEDON. This vaſt and diſcordant tribe makes up the chief part of a natural ſyſtem of arrangement, though indeed the families which have only one cotyledon, or, more properly, for the moſt part, none at all, are likewiſe conſiderable in number and importance, as the natural orders of Palms, Lilies, Orchiſes, Graſſes with their allies, and perhaps all the Linnæan claſs *Cryptogamia,* Moſſes excepted. The latter have numerous and compound cotyledons, though otherwiſe cloſely related to plants that have none. So alſo the Fir tribe, *Pinus*, &c. have numerous cotyledons, though in every other point agreeing with genuine *dicotyledones.* No natural ſyſtem of botanical arrangement can therefore in future ſet out, as they have all hitherto done, with making the diſtinction abſolute between *Acotyledones*, *Monocotyledones*, and *Dicotyledones ;* ſtill leſs can the *Polycotyledones* form a ſeparate aſſociation together ; indeed this laſt has never been attempted.

The two-ſeed-lobes of the *Dicotyledones*, like the numerous ones of firs and moſſes, uſually riſe out of the ground as ſoon as the root has fixed itſelf in the earth, witneſs the Lupines ; but ſome other plants, even of the ſame natural order, as many Vetches, never raiſe their cotyledons above the ſurface. Thoſe cotyledons which appear above-ground aſſume the colour and functions of leaves, of which the Radiſh, Parſley, and French-bean are inſtances ; while others remain but little altered

altered in the earth till they decay, as may be ſeen in the Horſe-cheſnut and Garden Naſturtium or *Tropæolum*. Whatever difficulties may exiſt in a claſſification founded on the organs in queſtion, the diſtinction between plants furniſhed with two cotyledons and thoſe that have only one or none, is, to all intents and purpoſes of arrangement or phyſiology, more abſolute and deciſive than any other general character hitherto detected. S.

DICRANUM, (διχρανον, a *fork*, from δις, *double*, and κερας, *a horn, ſummit*, or *point*, expreſſive of the two ſharp points into which each tooth of the fringe ſurrounding the mouth of the capſule is cloven.) Fork-moſs. Hedw. Fund. v. 2. 91. t. 8. f. 41, 42. Schreb. 759. Sm. Fl. Brit. 1201. Swartz. Muſc. Suec. 31. (Fiſſidens; Hedw. Fund. v. 2. 91. Bryi Mnii et Hypni ſpecies variæ, Linn.) Claſs and order, *Cryptogamia Muſci*. Nat. Ord. *Muſci*.

Eſſ. Ch. Capſule oblong. Fringe of ſixteen flat cloven teeth, a little inflexed.

The Hedwigian ſyſtem of moſſes, by taking into conſideration the ſtructure of their fringe or *periſtomium*, has very happily ſeparated from thoſe which have a double fringe, ſuch as have only a ſimple one, and is in no reſpect more happy than in the eſtabliſhment of genera on the number and ſtructure of the teeth which compoſe that ſimple fringe. Among the reſt *Dicranum* is diſtinguiſhed from all the reſt by its teeth being all cloven about half way down, regularly and uniformly for the moſt part; for there are ſcarcely two or three ſpecies in which ſome of the teeth are found unequally three-cleft. Such exceptions by no means invalidate the generic character. By this mark are brought together from the *Bryum* and *Mnium* of Linnæus principally, and more ſparingly from his *Hypnum*, a great number of moſſes, much more naturally allied to each other than to any with which they had previouſly been aſſorted, and now conſtituting by themſelves, and their recently diſcovered allies, ſo vaſt a genus, that the moſt able cryptogamic botaniſt muſt ſtand appalled at the number and intricacy of its ſpecies. Of theſe about 100 may be collected from various authors, but poor muſt be the herbarium which cannot ſupply ſeveral that are nondeſcript. We ſhall not bewilder the reader in this labyrinth, from which without the help of elaborate and numerous figures we could not extricate him. We ſhall attempt only a view of the leading features of this genus, and of its principal ſpecies.

The uſual habit of a *Dicranum* is marked by crowded ſlender or awl-ſhaped, moſtly ſingle-ribbed and entire, leaves, thoſe ſpecies which compoſe the genus *Fiſſidens* of Hedwig chiefly having two-ranked compreſſed and dilated foliage. In theſe the female flower is often lateral, but in the bulk of the genus terminal, the fruit-ſtalk becoming lateral in conſequence only of the ſubſequent extenſion of the ſtem beyond it. The capſule is often ſmooth, in ſome inſtances deeply furrowed longitudinally. Lid various in length. Teeth ſtrong, frequently very red, ſtrongly furrowed tranſverſely, their tips ſlender and pale. The male flowers in the *Dicranum* of Hedwig are, according to him, on a diſtinct plant from the female, in the form of little round terminal heads; in his *Fiſſidens* they are axillary on the ſame plant with the capſules, and reſemble buds. The habits of theſe two genera are ſo different, that in this caſe, if in any, the Hedwigian principle, of taking the male flowers into conſideration for the generic characters of moſſes, might be admitted; but the difficulty of examining thoſe parts in all the ſpecies of ſo vaſt a genus, at that early period of growth when alone they are to be met with, is inſurmountable, nor can Hedwig be ſuppoſed to have ſeen them in a fifth part of his ſpecies, any more than Fabricius could examine the organs of the mouth in a fiftieth part of his inſects. Both of them muſt, after all, have frequently truſted to habit, general configuration, or to the more obvious Linnæan principles.

The 1ſt ſection of *Dicranum* in the *Species Muſcorum* of Hedwig, has the capſule without any *apophyſis* or pedeſtal, the fruit-ſtalks ſtraight, and the leaves curved to one ſide. Of this the chief are D. *ſcoparium*, Engl. Bot. t. 354, common on heaths and in woods; the more rare D. *majus*, t. 1409, found on rocks by the ſea near Bangor; the common but elegant little D. *heteromallum*, t. 1272, which makes a green velvet carpet on the ſhady paths of woods on a gravelly or ſandy ſoil.

The 2d ſection has leaves leſs accurately inclining to one ſide, in which we find D. *criſpum*, Engl. Bot. t. 1151; D. *varium*, t. 1215, and *rufeſcens*, t. 1216. The latter ſeems not to be known out of Britain. D. *aciculare* alſo ranges here, whoſe leaves are broader and more obtuſe than in moſt of the genus.

The 3d ſection has leaves ſpreading every way, and not curled by drying; their tips without hairs. To this belongs D. *purpureum*, abundant on walls and gravelly hills, (where its innumerable crimſon ſtalks are conſpicuous in the ſpring;) as well as ſeveral other European or American ſpecies partly akin to it.

The 4th has ſpreading leaves with hair-like points, as D. *latifolium*, Hedw. Crypt. t. 33, a native of North America, given by Mr. Dickſon to the younger Linnæus, and by him to Hedwig, who celebrates the gift and the donor in high terms.

Section 5th has ſpreading leaves, becoming curled or criſped when dry. The chief of theſe is the large and rare D. *ſpurium*, found, but without fruit, by the late Mr. Teeſdale, an able cryptogamiſt, on turfy moors in Yorkſhire. It is figured in Hedw. Crypt. v. 2. t. 30, and was thus named on account of its male flowers being thoſe of a *Fiſſidens*, gemmiform, though the habit is that of a true *Dicranum*. The teeth of the fringe are ſome of them occaſionally three-cleft. D. *polycarpum*, another *Fiſſidens* of Hedwig, Crypt. v. 2. t. 31. likewiſe ranges here.

In ſection 6th the fruit-ſtalks are incurved, the capſule, as before, without an apophyſis. Among which are D. *flexuoſum*, Engl. Bot. t. 1491, (Bryum flexuoſum of Linnæus,) frequent in alpine ſtations; the elegant Weſt-Indian D. *cygneum*, Hedw. Sp. t. 37, and *introflexum*, t. 29.

Section 7th has an *apophyſis* or gland-like baſis to the capſule, as D. *cerviculatum*, Engl. Bot. t. 1661, found on turfy heaths in England, Germany, and Switzerland, a very elegant little moſs; D. *Celſii*, Hedw. Sp. t. 33, (Bryum Celſii of Linnæus,) found in Sweden, and very rarely in Scotland.

Theſe ſections not being altogether natural, nor always eaſy to define, they have not been attended to in the Flora Britannica, but the ſpecies have been attempted to be diſpoſed more naturally, not however with perfect accuracy, for ſuch muſt be the fruit of time and repeated enquiries.

The 8th ſection of this genus, the Fern Fork-Moſſes, may be defined, as in Fl. Brit., with compreſſed leaves, ſpreading in two ranks; and theſe form a very natural and beautiful family. The chief are; D. *viridulum*, Engl. Bot. t. 1368, the ſo much diſputed *Bryum viridulum* of Linnæus, one of the ſmalleſt of moſſes; D. *bryoides*, t. 625, which ſome able botaniſts ſtill confound with D. *oſmundioides*, t. 1662; D. *taxifolium*, t. 426, which is not uncommon in moiſt ſhady places, old gardens, &c.; and the larger more

conſpicuous D. *adiantoides*, t. 264, found in watery boggy ground.

From this genus the learned Mr. Turner has removed D. *ſciuroides* of Fl. Brit. to *Pterogonium*, on account of its lateral fruit-ſtalks and their ſcaly ſheaths; and he is followed in Engl. Bot. t. 1903. D. *pulviniatum* of Swartz and Fl. Brit. is alſo removed to *Grimmia* in Engl. Bot. t. 1728; and D. *viridiſſimum* proves to be a *Gymnoſtomum*; ſee Engl. Bot. t. 1583. It is proper alſo to mention that D. *calliſtomum*, Fl. Brit. and of Dickſon, is found not to differ from *rigidulum*, Engl. Bot. t. 1439; while the Angleſea plant of the Rev. H. Davies, from which the full deſcription was made, is D. *varium*.

To compenſate in part for theſe defalcations, we have to announce, that D. *longifolium*, Hedw. Crypt. v. 3. t. 9, is found in Scotland by Mr. George Don; a ſpecies of which we had no certain intelligence, as Britiſh, when the 3d vol. of Fl. Brit. was publiſhed. S.

DICRICH. See DIECKIRCH.

DICROTUS, in *Natural Hiſtory*, a word uſed by the ancients to expreſs the deer or ſtag when in its third year's growth. It was called nebus by the ancient Greeks in the firſt year, puttolea in the ſecond, dicrota in the third, and in the fourth, and all its life afterwards, ceraſtes.

DICROTUS, from δις, *twice*, and κρεω, *I ſtrike*, in the *Medicinal Writings of the Ancients*, the epithet given to a peculiar ſort of pulſe, which Dr. Nihill calls very properly in Engliſh the rebounding pulſe. In this kind of pulſe the artery beats as it were double; and is eſteemed a certain ſign of a future critical hæmorrhage by the noſe. See PULSE.

DICTAMNUS, in *Botany*, (ſo called by Linnæus after the διϰταμον or διϰταμνος of Theophraſtus and Dioſcorides, which is moſt aſſuredly a different plant; neither does his derivation of the name in the Philoſophia Botanica, from τιϰτειν, to bring forth, confirm the propriety of his application of it. However ſuitable that explanation might be to the real Dittany of Crete, *Origanum Dictamnus*, and the hiſtory of its expelling arrows from the wounded goats, it has no reference to our plant. Hence Tournefort, and of late Gærtner, have called the latter *Fraxinella*, a word intolerable, as a generic name, to Linnæan ſcholars. Some have taken the plant in queſtion for the ἱερακιον of Dioſcorides, but with no great appearance of probability; nor has Dr. Sibthorp, though he gathered it in Greece, left us any information concerning its Greek name, antient or modern.) Fraxinella, or Baſtard Dittany. Linn. Gen. 209. Schreb. 287. Willd. Sp. Pl. v. 2. 541. Juſſ. 297. (Fraxinella; Gærtn. t. 69.) Claſs and Order, *Decandria Monogynia*. Nat. Ord. *Multiſiliquæ*, Linn. *Rutaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of five ſmall oblong pointed leaves, deciduous. *Cor.* Petals 5, ovato-lanceolate, pointed, furniſhed with claws, unequal; two of them twiſted upwards; two ſtanding obliquely at the ſides; and one bent downwards: all dotted with reſinous points. *Stam.* Filaments 10, unequal, awl-ſhaped, about as long as the petals, and bent downwards below, the two lateral ones, ſprinkled with reſinous glands; anthers ſquare, aſcending, ſimple. *Piſt.* Germen ſuperior, ſlightly ſtalked, with five angles, depreſſed at the top; ſtyle ſhort, declining, recurved; ſtigma acute, aſcending. *Peric.* Capſules five, connected by their inner margin, compreſſed, pointed, radiating, each of two valves. *Seeds*, two in each cell when ripe, ovate, poliſhed, lodged in a common, bivalve, elaſtic, notched arillus.

Eſſ. Ch. Calyx of five leaves. Petals five, unequal, ſpreading. Filaments beſprinkled with reſinous glands. Anthers terminal, ſimple. Capſules five, conjoined.

The only ſpecies is D. *albus*. Linn. Sp. Pl. 548. Willd. Sp. Pl. v. 2. 541. Jacq. Auſtr. t. 428. Bauh. Pin. 222. (Fraxinella; Ger. em. 1245.) A native of ſhady ſomewhat mountainous places in Germany, France, Switzerland, Italy, and Greece, commonly cultivated in the open borders of our gardens without any particular care, flowering in June and July. The roots are perennial. Stems annual, a foot or two high, ſimple, leafy in their middle part, each terminating in a large upright rigid panicle of very handſome roſe-coloured flowers, occaſionally white. The leaves are pinnate, ſomewhat reſembling thoſe of the aſh, whence the name *Fraxinella*. The ſpecific name *albus* alludes to the whiteneſs of the root. The whole plant abounds with a ſtrong aromatic eſſential oil, ſmelling like lemon peel, with a reſinous flavour, to many perſons very agreeable. In hot dry weather, a highly inflammable vapour is emitted by the flowers or their viſcid ſtalks, which explodes on the approach of a flame. S.

DICTAMNUS *capenſis*. See CALODENDRUM.

DICTAMNUS *creticus*. See ORIGANUM.

DICTAMNUS *falſus*, or *Pſeudodictamnus*. See MARRUBIUM.

DICTAMNUS, in *Gardening*, comprizes a plant of the herbaceous, hardy, perennial, flowering kind; the Fraxinella, or White Dittany, (D. *albus*). It riſes from one to two feet in height, with ſeveral ſtems, and the whole plant, when gently rubbed, emits an odour ſimilar to that afforded by lemon-peel, but when bruiſed, has ſomething of a balſamic ſmell.

It has varieties with white flowers, with red and purple ſtriped flowers, and with ſhort ſpikes of flowers.

Method of Culture.—Theſe plants may be increaſed by ſowing the ſeeds in the beds, borders, or other parts of pleaſure-grounds or gardens, where they are to remain, in the beginning of the Autumn, ſoon after they become ripe, or in the Spring; but the former is the beſt ſeaſon, as the plants riſe ſtronger, and with more certainty. The plants ſhould afterwards be kept perfectly clean from weeds, and have their ſtems cut down and cleared away every year in the Autumn, as well as the earth dug round them in the early Spring. Some, however, adviſe the roots of the plants, in the firſt Autumn, to be taken up and planted out in ſmall beds, at ſix or eight inches diſtance each way, to ſtand two or three years, till they are ſtrong enough to flower, when they are to be carefully taken up in the Autumn, and placed where they are to remain. They continue for a great length of time, and require little culture, except that of being kept free from weeds, and trimmed as above in the Autumnal ſeaſon.

They are plants which are well ſuited to the middle parts of beds, borders, clumps, and other compartments of ornamented grounds.

DICTATE, DICTAMEN, in the *Schools*, a ſuggeſtion, motion, or ſentiment of a man's conſcience. A good action becomes evil, if done contrary to the dictates of one's own conſcience.

DICTATE, *Dictata*, is likewiſe uſed in the *Schools* for a leſſon, or exerciſe, wherein the maſter reading, or ſpeaking ſomething, the ſcholars take it down in writing after him. Here the act of the maſter is likewiſe called dictating.

DICTATOR, a Roman magiſtrate, created by the ſenate, or people, on ſome extraordinary and eminent occaſion, to command, with ſovereign authority, for a certain time, ordinarily limited to ſix months, though the office was ſometimes continued to twelve.

The nomination of this magiſtrate appears to have been aſſigned by law to either of the two conſuls; but the choice

which they were taxed in the ſame manner and conjointly with the reſt of the commons; and have ever ſince been repreſented in parliament by the ſame perſons, which has more *embodied* them with the laity, and prevents the ſetting up of a church intereſt diſtinct from that of the people. It is remarkable, that this very important alteration in the ſtate of the kingdom was made *without any law*, by agreement with the clergy. (Littleton's Hiſt. Hen. II. vol. iii.)

In the parliament of Ireland, originally formed on the model of that of England, the clergy continued to be members of the houſe of commons, till they were excluded by an act of parliament, 28 Hen. VIII. A. D. 1536, becauſe they ſupported the authority of the pope, and obſtructed the reformation of the church. Whilſt the clergy continued to grant their own money in their convocations, their grants were not effectual till they were confirmed in parliament. In the 15th century the clergy of England had great influence in all the public councils of the kingdom, and particularly in parliament: they conſtantly reſided in the kingdom, and were preſent in theſe councils; while the nobles and great men were engaged in warlike expeditions into France or Scotland. Beſides all the archbiſhops and biſhops, twenty-five abbots and two priors were ſummoned to every parliament, and ſometimes many more; ſo that the ſpiritual lords were generally double the number of the temporal lords in the houſe of peers. (Prynne's regiſter of writs, vol. i. & iv.) This enabled the prelates to procure ſanguinary laws againſt heretics, and to ſecure the immenſe poſſeſſions of the church, together with all her abſurd errors and wretched ſuperſtitions, from all attacks. 1 Hen. IV. c. 15. 2 Hen. V. c. 7.

CONVOLVULI, in *Botany*, the tenth natural order of dicotyledonous hypogynous plants, in the ſyſtem of Juſſieu, with the following character. *Calyx* five-cleft, moſt frequently permanent. *Corolla* regular, commonly with a five-cleft border. *Stamens* generally five, inſerted at the baſe of the corolla, and alternating with its ſegments. *Style* one, or definitely divided; when one, with a ſtigma either ſimple or divided; when more than one, with as many ſimple ſtigmas as there are diviſions. *Fruit* capſular, often three-celled, more rarely two or four-celled; cells with one or more ſeeds. *Seeds* marked with an umbilical eye at the baſe, ſomewhat oſſeous, and affixed below to the central partition; valves free, with their edges adjoining to the angles of the partition; radicle of the arched corculum inferior. (Corculum ſhut up by the periſperm?) *Stems* ſhrubby, or more frequently herbaceous; many twining; many lacteſcent. *Leaves* alternate, very rarely almoſt oppoſite, (always ſimple, Vent.). This order is nearly allied to the Borragineæ and Polemonia, in its regular five-cleft pentandrous corolla, and alternate leaves; but differs from the latter, in having the partition adjoining to the edges, not to the middle of the valves; and from the former, in the fruit not being gymnoſpermous. Juſſieu aſſigns to it the following genera: 1. With a ſingle ſtyle. Maripa, Aubl.; mouroucoa, Aubl.; retzia, Thunb.; endrachium, (humbertia, Commers.); convolvulus, Linn.; ipomæa, Linn. 2. With ſeveral ſtyles. Evolvulus, Linn.; nama, Brown and Linn.; hydrolea, Linn.; ſagonea, Aubl.; creſſa, Linn. 3. Allied to the convolvuli. Cuſcuta, Linn.; diapenſia, Linn.; loeſelia, Linn.

Ventenat has changed the name of the order to convolvulaceæ, and has included in it only convolvulus, ipomæa, evolvulus, and creſſa; entirely omitting marupa, mouroucoa, retzia, endrachium, nama, hydrolea, and ſagonea; and removing cuſcuta to his undetermined plants, and diapenſia and loeſelia to the polemonia, his polemonaceæ. La Marck's natural family of liferons correſponds exactly with the firſt two ſections of Juſſieu.

CONVOLVULUS, (ſo called, *a convolvendo*, becauſe many of the ſpecies are twining). Linn. Gen. 215. Schreb. 287. Willd. 323. Lam. Illuſt. 296. Gært. 780. Juſſ. 133. Vent. ii. 396. Claſs and order, *pentandria monogynia*. Nat. Ord. *Campanaceæ*, Linn. *Convolvuli*, Juſſ. *Convolvulaceæ*, Vent.

Gen. Ch. *Cal.* perianth five-cleft. *Cor.* monopetalous, bell-ſhaped or funnel-ſhaped, plaited; border generally ſpreading, more or leſs five-lobed. *Stam.* filaments five, awl-ſhaped, ſhorter than the corolla, approximating at the baſe. *Piſt.* germ ſuperior, roundiſh; ſtyle filiform; ſtigma ſimple or bifid. *Peric.* capſule ſurrounded by the calyx, roundiſh; one, two, three, or four-celled; one, two, three, four, or many-valved. *Seeds* one or two in each cell.

Eſſ. Ch. Five-cleft. Corolla bell or funnel-ſhaped. Stigmas one or two. Pericarp a capſule, or dry berry. Seeds one or two in each cell.

Obſ. Authors often call the calyx five-leaved, when it is very deeply five-cleft.

* *Stems twining.*

Sp. 1. C. *arvenſis*. Linn. 1. Mart. 1. Deſrouſſeaux, Encyc. 2. Lam. Ill. 2001. Willd. 1. Bauh. Pin. 294. Flor. Dan. tab. 459. Curt. Flor. Lond. 2. 13. Eng. Bot. 312. (C. minor; Bauh. Hiſt. 2. 157. C. purpureus; Lob. Obſ. 340. fig. 2. C. minor arvenſis, flore roſeo; Tourn. Inſt. 83. Smilax levis minor; Ger. Emen. 861. Helxine foliis ſagittatis; ciſſampelos; Mat. 1011. Camer. Epit. 753.) "Leaves arrow-ſhaped; lobes acute; flowers generally ſolitary; bractes minute, awl-ſhaped, remote from the flower." *Root* perennial, creeping, ſtriking deeply into the ground, not eaſily extirpated. *Stems* numerous, angular. *Leaves* alternate, petioled, ſmoothiſh. *Flowers* fleſh-coloured, ſometimes white, ſweet-ſcented, opening only in clear weather; peduncles axillary, generally one-flowered, thickened above. A troubleſome weed in cultivated ground, twining cloſely about the culms of wheat, and other kinds of corn, and thence in many parts of England called bind-weed. Its juice is ſlightly purgative. The bloſſoms give a deep yellow or orange tincture to water, which is heightened by alum and alkalis. A native of Great Britain, and moſt parts of Europe. 2. C. *auriculatus*. Deſr. 3. Lam. 2002. (C. arvenſis β; Linn. C. minimus, anguſto auriculato folio; Bocc. Muſ. tab. 33. Pluk. Alm. 116. tab. 24. fig. 3. C. arvenſis minimus; Rai. Syn. 276.) "Leaves linear, haſtate-acuminate; lobes entire." Diſtinguiſhed from the preceding by its narrow elongated leaves, longer petals, and bractes placed nearer the flower. A native of Great Britain, and other parts of Europe: found by Commerſon in the Iſle of France, where it is ſuppoſed to have been brought with wheat from Perſia. 3. C. *ſepium*. Linn. 2. Mart. 2. Deſr. 1. Lam. 1. Willd. 2. Flor. Dan. tab. 458. Curt. Flor. Lond. 1. tab. 13. Eng. Bot. 313. (C. major, albus; Bauh. Pin. 294. Tourn. Inſt. 82. Smilax lœvis major; Ger. Emen. 861.) "Leaves arrow-ſhaped; lobes truncate; peduncles ſquare, one-flowered; bractes larger than the calyx, and cloſe to it." β americanus; with a fleſh-coloured flower. Bot. Mag. 732. *Root* perennial, about the thickneſs of a gooſe-quill, white, creeping, not eaſily eradicated. *Stems* numerous, from ſix to ten inches high, or more, angular, ſmooth, not much branched. *Leaves* alternate, petioled, dependent. *Flowers* large, generally white, ſometimes fleſh-coloured; nectary a yellow gland, ſurrounding the baſe of the germ. A native of Great Britain,

From the circumſtance above mentioned, the cuſtom was probably derived of declaring the dictator in the night, which is often mentioned by Livy (lib. iv. c. 21. lib. viii. c. 23, lib. ix. c. 38.)

The conſtitution of the Roman republic is praiſed by Polybius (l. vi.) as a happy mixture of monarchy, ariſtocracy, and democracy; but the dictatorſhip reduced it under a kind of domination more properly tyrannical than regal. In Rome, a ſingle conſul, agreeing with the ſenate to name a dictator, without the concurrence, and againſt the will of the people, might ſubject, at any time, the liberty and the life of every Roman citizen, to the arbitrary power of one man, ſet above all the laws, and in no way reſponſible for the exerciſe of his ſovereignty, to the juſtice of the ſtate. Indeed, after the end of the ſecond Punic war, the ſenate itſelf became ſo jealous of the danger of this office, that, for 120 years before Sylla took it, no dictator was appointed. The manner in which he choſe to have it conferred on him was as follows: both the conſuls of the year of Rome 670, B. C. 84, having periſhed in the war which Sylla and his friends made againſt them, he notified to the ſenate, that agreeably to the cuſtom of their anceſtors, in ſuch caſes, they ſhould create an *interrex* to hold the *comitia* for electing new conſuls. They named to that office the preſident of the ſenate, Lucius Valerius Flaccus; to whom Sylla wrote, and bade him report his opinion to the people, that the preſent ſtate of affairs required the appointment of a dictator; not for the term of ſix months, but till the whole commonwealth, and every part of the empire, which the civil wars had ſhaken, ſhould be more firmly ſettled, and brought into better order; adding, at the end of his letter, that, if the ſenate approved it, he offered himſelf to do the republic this ſervice. His offer was underſtood to be a command; he therefore was named dictator by the *interrex*, without any term being fixed for the expiration of his office; and thus, ſays Appian (De Bell. Civ. l. i.) "the dictatorſhip, which had before been a tyranny limited to a ſhort time, this reſtraint being taken off, the tyranny became compleat." The dictator was not content with this indefinite prolongation of his power; but cauſed a law to be propoſed by the *interrex* to the people, which "ratified all his acts, whatever they might be, and authoriſed him to put to death, without a trial, any citizen of Rome, according to his pleaſure." Cicero calls this "the moſt unjuſt, and the moſt unlike a law, that had ever been made," and he conſiders it "as null and void in itſelf." Yet to ſuch an extreme degree of ſervility were the people and the ſenate reduced, that it was enacted without the leaſt oppoſition; and Sylla rewarded Flaccus for having been the propounder of it, by naming him to the dignity of his general of the horſe. Cæſar was the next perpetual dictator to Sylla. After Cæſar there were no more dictators; for Antony, in the year of Rome 710, B. C. 44. aboliſhed this office; and in doing it, he reſerved the honour of this action entirely to himſelf. For he did not propoſe the affair, according to uſual cuſtom, to the deliberation of the ſenate, but he brought the decree with him ready drawn up. On which the title and office of dictator were for ever aboliſhed, with imprecations againſt any one who ſhould attempt to revive them, and a power for any citizen to attack and kill him with impunity. This, as may be evidently perceived, was indirectly caſting a ſlur on Cæſar's memory, and not only eſtabliſhing and confirming the preſent liberty, but ſecuring it againſt any future attempts.

After the famous battle of Thraſymenus, an. U. C. 537, B. C. 217, which was the third defeat of the Romans, in leſs than a year after Hannibal had entered Italy, the Romans were in great conſternation, and entertained apprehenſions for the city itſelf. But becauſe the conſul to whom alone it appertained to nominate a dictator, was abſent, and it was not eaſy to carry any meſſage to him, as the Carthaginians occupied all the paſſes, Q. Fabius Maximus was elected *Prodictator*. He was allowed to be the only perſon whoſe greatneſs of ſoul, and gravity of manners, correſponded to the dignity and majeſty of that office; and the more, as he was ſtill of an age, in which the mind is of ſufficient vigour to execute the deſigns it has formed, and in which reſolution and boldneſs are tempered with prudence. Fabius demanded permiſſion of the people to ride in the army; which, by an ancient law, the dictator was expreſsly forbidden to do.

Dionyſius Halicarnaſſeus derives the word dictator *ab edicendo*, becauſe they ordained or appointed what they pleaſed. But Varro will have the word taken hence, that the conſul named him, which the Latins call dicere, lib. iv. De Lingua Latina. "Dictator quod a conſule dicebatur, cujus dicta audientes omnes eſſent."

DICTE, in *Ancient Geography*, a mountain of the iſland of Crete, now called *Sethia*, and alſo *Laſthi*, next in height to mount Ida, and covered for a great part of the year with ſnow; whence it is denominated by Strabo, Pliny, and Ptolemy, the white mountain. However, cypreſs-trees grew there anciently amidſt the ſnow, and throve as well as in the vallies. This mountain obtained its name from Dictynna, a nymph of Crete, who is ſuppoſed firſt to have invented hunting-nets, and to have been called Dictynna on that account; having before been named Brito-martis. This mountain was conſecrated to Jupiter; and hence he obtained the appellation of DICTÆUS, as well as from a cave of this name in the iſland in which he had been concealed.

DICTIDIUM, a town of Greece, ſituated near mount Athos.

DICTION, the phraſe, elocution, or ſtyle of a writer or ſpeaker.

The diction or language of an orator ſhould be pure, proper to the ſubject, rich without affectation, ſtrong and cloſe without dryneſs, and ſuitable to the perſon, time, place, and audience. See ELOCUTION, and STYLE.

The diction of a drama is accounted the fourth of the eſſential parts thereof, the other three being the fable, the manners, and the ſentiment; it is of the leaſt importance of any; yet muſt peculiar care be taken herein to make every paſſion ſpeak its proper language. See DRAMA.

DICTIONARY, a collection, or catalogue of all the words of a language, or art, with their ſignifications, ranged in order of the alphabet.

What the Latins, and we after them, call dictionary, the Greeks call Lexicon.

For the proper character, nature, office, &c. of a dictionary, ſee the preface to this work. See alſo VOCABULARY.

The moſt ancient dictionaries for the Latin tongue, are, that called Papias, compiled by Solomon, abbot of St. Gall, biſhop of Conſtance, who lived about the year 1409; another made in 1469, called Gemma Vocabulorum; a third in 1502, called Gemma Gemmarum: and a fourth by Dionyſius Neſtor, a Cordelier.

The moſt celebrated old Latin dictionary is that of Ambroſe Calepine, a hermit of St. Auguſtine at Bergamo, and ſon of the count of Calepine. Conrad Geſner is ſaid to have augmented this with four thouſand words. Paulus Manutius increaſed it ſtill more; and Paſſerat after him; and yet Matthias Martinius made two volumes of their omiſſions.

There is another noted Latin dictionary of Criſpinus: to ſay nothing of Cowper, Holyoake, Gouldman, Littleton, Cole, Ainſworth, and many others of leſs conſideration.

For the Greek, we have thoſe of Henry Stevens and

ered, ſhorter than the petiole." *Root* perennial. The young branches, petioles, leaves, peduncles, and calyxes, cloathed with a ſilky ſhining down. *Stem* cylindrical, woody, almoſt ſmooth. *Leaves* broad-oval, alternate, acute, entire, nerved, about twice the length of the petioles. *Peduncles* axillary, ſolitary, with two awl ſhaped bractes about the middle; calyxes ſhort; two inner leaves ſmaller; corollas at leaſt two inches long, funnel-ſhaped. A native of the Philippine iſlands. Specimen in the herbarium of Juſſieu. 16. C. *chenopodioides*. Deſr. 21. Lam. 2020. "Villous; leaves egg-ſhaped, ſerrate-ſinuated; flowers ſolitary, nearly ſeſſile." *Stems* ſlender, weak, cylindrical. *Leaves* an inch long; petioles about half their length, channelled. *Peduncles* axillary, ſolitary; bractes two, ſmall, ſiliform, rather long; leaves of the calyx egg-ſhaped, acute, corollas narrow, tabular. In the herbarium of La Marck. 17. C. *medium*. Linn. Sp. Pl. 4. Mart. 6. Deſr. 10. Lam. 2009. Willd. 12. "Leaves linear, haſtate-acuminate; auricles toothed; peduncles one-flowered; calyxes arrow-ſhaped." Plant ſmooth in all its parts. *Root* annual. *Stems* very ſlender. *Peduncles* axillary, ſolitary, often bent in the middle at the origin of the two bractes; upper half angular, thicker; three outer leaves of the calyx large, nearly as long as the peduncles, acute, arrow-ſhaped at the baſe, like thoſe of campanula medium; auricles terminated by two or three ſmall teeth; two inner ones entire, acute, a little ſhorter; corolla not longer than the calyx. A native of Madagaſcar and the Eaſt Indies. 18. C. *filicaulis*. Mart. 88. Willd. 13. Vahl. Sym. 3. 24. "Leaves linear-lanceolate, obtuſe, mucronate, dilated and toothed at the baſe; calyx leaves oblong." *Root* annual. *Stem* herbaceous, filiform, branched. *Leaves* on very ſhort petioles, diſtant, two inches long or more, tender, veined, quite ſmooth. *Peduncles* axillary, filiform, thicker at the top; bractes two, oppoſite, awl-ſhaped, above the middle of the peduncle; calyx-leaves mucronate, ſmooth; ſtigma ſimple, bluntiſh. A native of Guinea. 19. C. *tridentatus*. Linn. Sp. Pl. Ed. 1. Mart. 76. Deſr. 12. Lam. 2011. Willd. 14. Pluk. Alm. 117. tab. 276. fig. 6. & Mant. 117. tab. 167. fig. 5. (Evolvulus tridentatus; Linn. Sp. Pl. Ed. 2. Fendera-claudi; Rheed. Mal. 11. 133. tab. 65.) "Leaves ſpatulate-linear, three-toothed at the tip, dilated and toothed at the baſe; calyx-leaves elliptical, cuſpidate." *Root* annual. *Stems* filiform, ſmooth, ſlightly ſtriated, almoſt ſimple. *Leaves* alternate, about half an inch long, ſmooth; petioles about a line long. *Flowers* purpliſh at the baſe, with a yellowiſh white border; peduncles axillary, ſolitary, one-flowered, longer than the leaves, with two ſmall bractes near their ſummit. A native of the Eaſt Indies. Introduced into England in 1778, by ſir Joſeph Banks. 20. C. *anguſtifolius*. Mart. 89. Deſr. 32. Lam. 2030. Willd. 15. (Ipomæa anguſtifolius; Jacq. ic. 2. tab. 317.) "Leaves linear, haſtate, obtuſe, mucronate, ſmooth; auricles generally entire; peduncle one-flowered." *Root* ſpindle-ſhaped, riſing about an inch above the ſurface of the ground, with the appearance of a ſlender, ſimple, erect, leafleſs ſtem. *Stems* ſeveral, ſcarcely a foot high, a little twining, almoſt ſimple, filiform, weak. *Leaves* an inch long, about a line broad, numerous, on very ſhort petioles. *Flowers* yellow, longer than the calyx; peduncles axillary, ſolitary, ſhorter than the leaves, with two awl-ſhaped bractes, about the middle, upper half thicker; calyx-leaves connivent, lanceolate, mucronate; corolla funnel-ſhaped; border very open; diviſions egg-ſhaped, obtuſe; ſtigma globular, didymous. *Capſule* two-celled. A native of Guinea and the Eaſt Indies. 21. C. *ariſtolochifolius*. Mill. Houſton MSS. "Leaves haſtate-lanceolate; auricles rounded; peduncles many-flowered." *Root* annual. *Stem* ten feet high, ſlender. *Flowers* yellow, in ſmall cluſters, on long peduncles. *Capſules* trigonous, three-celled. *Seeds* two in each cell. Seeds ſent to Mr. Miller from Carthagena in New Spain. 22. C. *Adanſonii*. Deſr. 82. Lam. 2080. "Leaves haſtate, linear,; ſtipules in pairs, ſomewhat ſiliform; calyx muricated." *Stems* herbaceous, weak, a little villous. *Leaves* alternate, diſtant, petioled, entire, ſmooth, from three to four inches long; ſtipules about an inch long. *Flowers* near two inches long, axillary; peduncles nearly the length of the petioles, ſmooth, with two ſmall bractes about the middle; calyx-leaves egg-ſhaped, rough, with ſharp tubercles. A native of Senegal. 23. C. *japonicus*. Mart. 7. Deſr. 6. Lam. 2005. Willd. 16. Thunb. jap. 85. (Kos and Kudſi vulgo Firaga wo; Kempf. Amæn. 5. 856.) "Leaves haſtate, lanceolate, acute; lateral lobes one-toothed; peduncles one-flowered; ſtem ſimple." *Stems* filiform, ſmooth. *Leaves* alternate, almoſt unilateral, petioled, ſmooth; middle lobe an inch long, lanceolate, entire, acute; ſide ones a little reflexed, ſhorter. *Flowers* axillary, ſolitary; peduncles as long as the leaves, filiform, ſmooth; calyx-leaves egg-ſhaped, acute, entire, ſmooth. A native of Japan. 24. C. *ebracteatus*. Deſr. 7. Lam. 2006. "Leaves cordate-arrow-ſhaped, obtuſe behind; peduncles ſhorter than the petiole, without bractes." Whole plant, except the corolla, cloathed with ſhort white hairs. *Stems* ſcarcely a foot and a half long, ſlender. *Leaves* alternate, acute. *Flowers* white, ſmall; peduncles one or two-flowered; ſegments of the calyx five; two outer ones broader; ſtigmas two, globular, purpliſh. Native country unknown. Cultivated in the botanic garden at Paris. 25. C. *leucanthus*. Deſr. 8. Lam. 2007. (Ipomæa leucantha; Jacq. Coll. 2. 280. ic. 2.) "Leaves heart-ſhaped, acuminate: peduncles ſhorter than the petiole." *Root* annual. *Stems* about four feet high, ſlender, cylindrical, branched, reddiſh, and ſomewhat rough towards the bottom. *Leaves* alternate, entire, or ſlightly ſcolloped, ſmooth. *Flowers* white; peduncles axillary, ſolitary, an inch long, erect, cylindrical, ſmooth, one-flowered: calyx leaves mucronate, a little open at the ſummit, ciliated at the baſe; corolla funnel-ſhaped: anthers purpliſh; ſtigma two-lobed. A native of America in the torrid zone. 26. C. *fruticuloſus*. Deſr. 9. Lam. 2008. "Shrubby; leaves ſomewhat heart-ſhaped at the baſe, linear, lanceolate, petioles ſhort; flowering branches, thick ſet with leaves." *Root* perennial. *Stems* three or four feet high, cylindrical, ſlender. *Leaves* not more than two lines broad, ſloped at the baſe, on very ſhort petioles. *Flowers* with five purple rays; peduncles larger than the petioles, ſcarcely the length of the flowers; bractes two, ſmall, awl-ſhaped, unequal, ſituated nearer to the ſtem than to the calyx; calyx ſmooth; corolla ſhallowly five-lobed. A native of the Canary iſlands, flowering in April and May. 27. C. *dentatus*. Mart. 90. Willd. 17. Vahl. Symb. 3. 25. "Leaves haſtate, ſmooth; auricles toothed; peduncles many-flowered, muricated." *Stem* cylindrical, ſmooth. *Leaves* ſcarcely an inch long, ſomewhat heart-ſhaped at the baſe; middle lobe lanceolate, quite entire; ſide ones roundiſh, unequally four or five-toothed; petioles filiform, often ſomewhat muricated towards the baſe. *General peduncles* ſpreading, thicker, and a little longer than the petioles; partial peduncles in threes; that in the middle one-flowered; ſide ones with two or three pedicelled flowers; both muricated; rigid; calyx-leaves oblong, obtuſe, mucronate, equal. A native of the Eaſt Indies, found by Schumacher. 28. C. *haſtatus*. Mart. 79. Willd. 18. Vahl. Symb. 1. 15. Forſk. deſcr. 203. "Leaves lanceolate, haſtate; peduncles axillary, in pairs, two-flowered." *Stem* hairy. *Leaves* remote, quite entire, ſmooth on the upper ſurface, villous on the lower; au-

ricles rounded, ſometimes with one tooth behind: petiole half the length of the leaf. *Peduncles* ſhorter than the petiole, villous; calyx-leaves hairy, acuminate, patulous at the tip. A native of Egypt and Arabia. 29. C. *Sonneratii*. (C. haſtatus; Deſr. 11. Lam. 2010. Tala-neli; Rheed. Mal. 11. 113. tab. 55.) "Leaves linear, haſtate-acuminate; auricles toothed; calyx-leaves ſimple." Whole plant ſmooth. *Stems* very ſlender, ſlightly angular. *Leaves* about two lines broad, alternate, nearly ſeſſile. *Peduncles* longer than the flower, ſlender, one or two-flowered, often bent at the inſertion of the bractes, thicker upwards; bractes two, ſmall, awl-ſhaped, ſituated a little above the middle of the peduncle. *Flowers* yellowiſh-white, twice the length of the calyx; calyx-leaves egg-ſhaped, acute. A native of the Eaſt Indies, communicated to La Marck by Sonnerat. 30. C. *aſarifolius*. Deſr. 89. Lam. 2087. "Leaves kidney-ſhaped, broad, veined; peduncles one or two-flowered." *Stems* cylindrical, ſmooth, not much branched. *Leaves* alternate, large, entire, ſmooth, firm; petioles about two inches long, channelled. *Peduncles* longer than the petioles; bractes from two to four, ſmall, awl-ſhaped, ſituated almoſt cloſe to the flowers; calyx-leaves ſhort, egg-ſhaped, obtuſe, two outer ones ſmaller; corollas at leaſt two inches long, tubular; tube about half an inch diameter; border but little open, with five pointed diviſions; ſtigma capitate, didymous. A native of Senegal. 31. C. *tiliæfolius*. "Shrubby; leaves heart-ſhaped, rounded; younger ones ſomewhat tomentous; flower and fruit very large." *Stems* cylindrical, almoſt ſmooth. *Leaves* alternate, a little orbicular, entire; petioles about half the length of the leaves, channelled. *Flowers* large; peduncles not more than eight or ten lines long, axillary, ſolitary, one-flowered; calyx-leaves ſhort, obtuſe, almoſt round; corolla at leaſt three inches long, almoſt cylindrical; tube narrow as far as the length of the calyx, afterwards eight or ten lines in diameter; ſtigma capitate, two-lobed. *Capſule* about the ſize of a walnut, apparently two-celled. A native of the Iſle of France, and the Cape of Good Hope. Found by Commerſon. 32. C. *panduratus*. Linn. Sp. Pl. 5. Mart. 8. Deſr. 91. Lam. 2089. Willd. 19. (C. megalorrhizos; Dill. Elth. 101. tab. 85. fig. 99.) "Leaves, ſome heart-ſhaped, entire, others panduriform or three-lobed; peduncles longer than the petiole, about two-flowered." *Root* perennial, thick, ſpindle-ſhaped. *Stems* long, ſlender. *Leaves* diſtant, petioled. *Flowers* large, white, with the bottom of fine purple; peduncles axillary, ſolitary, from one to three-flowered; calyx-leaves ſhort, two outer ones ſhorter and narrower. *Capſule* two-celled. *Seeds* hirſute, one in each cell. A native of Carolina and Virginia, flowering from June to September. 33. C. *betonicifolius*. Mart. 72. "Leaves cordate-arrow-ſhaped, acute; peduncles one-flowered." *Stem* five or ſix feet high, ſlender. *Flowers* white, with purple bottoms; peduncles long, ſlender. A native of Africa, cultivated by Miller in 1730. 34. C. *bracteatus*. Mart. 91. Vahl. Sym. 3. 25. "Leaves heart-ſhaped, almoſt entire, and three-lobed, haſtate, attenuated; peduncles one-flowered; outer calyx-leaves bracte-ſhaped." *Stem* thinly beſet with ſhort hairs. *Leaves* two inches long; petioles ſhorter than the leaf, pubeſcent. *Peduncles* the length of the leaf, ſolitary; bractes two, laneeolate, acute, ſituated a little below the calyx; calyx pubeſcent; inner calyx-leaves oblong, bluntiſh, nerved; outer ones much broader, encloſing the others as between two bractes; corolla villous on the outſide, tender, ſilky; border five-cleft; ſtigma capitate, two-lobed, found in the Eaſt Indies by Koenig. 35. C. *bicolor*. Mart. 92. Willd. 21. Vahl. Symb. 3. 25. "Leaves heart-ſhaped, villous, ſomewhat angular-lobed at the baſe; peduncles one-flowered; outer leaves of the calyx reſembling bractes." *Stem* villous. *Leaves* acute, mucronate, not attenuated, nearly equal in length and breadth, one, two, or three-lobed at the bottom, villous on both ſides; very ſoftly villous, hoary, and obſcurely veined underneath; the younger ones ſilky. *Flowers* white, with a violet purple baſe; bractes, calyx, and corolla, as in the preceding ſpecies. Found in the Eaſt Indies by Schumacher. 36. C. *Geffroyenſis*. (C. bicolor; Deſr. 96. Lam. 2094.) Hairy; leaves ſomewhat heart-ſhaped, three-lobed, hoary underneath; peduncles many-flowered." On a ſuperficial view having the appearance of a bramble. *Stems* ſlender, cylindrical; beſet, as well as the petioles, peduncles, and calyxes, with blackiſh points, and hiſpid with rather long ſtiffiſh hairs. *Leaves* alternate, longer than their petioles, cloathed with fine recumbent hairs, green on the upper ſurface, hoary underneath; lobes oval, acute, entire. *Flowers* ſmall; peduncles axillary, ſolitary, thicker and longer than the petioles, dichotomous; bractes two, linear, awl-ſhaped, ſituated at each diviſion of the peduncles; calyx-leaves narrow, acute, rather long. Brought from Senegal by M. Geoffroy. 37. C. *trilobus*. Willd. 22. Thunb. prod. 35. "Leaves heart-ſhaped, villous, three-lobed; lobes egg-ſhaped, acute; peduncles one-flowered." A native of the Cape of Good Hope. 38. C. *ſubquinquelobus*. (C. trilobus; Deſr. 94. Lam. 2092. Ipomæa triloba; Linn.) "Lower leaves heart-ſhaped, three-lobed; upper ones ſomewhat five-lobed; peduncles three-flowered." *Root* annual. *Stems* two or three feet long, ſlender, ſlightly angular, ſmooth. *Leaves* alternate, generally ſhorter than their petioles; middle lobes of the lower leaves egg-ſhaped, obtuſe, mucronate, ſmooth; lateral lobes of the upper leaves with a deep ſinus, which makes them appear five-lobed. *Flowers* purple or violet; peduncles angular, nearly the length of the petioles; pedicels very ſhort, bractes ſmall, egg-ſhaped; calyx-leaves half the length of the corolla, ſmooth, egg-ſhaped, acute, connivent; corollas ſmall, cylindrical; border with five ſharp teeth. A native of South America, cultivated in the botanic garden at Paris. 39. C. *platanifolius*. Mart. 93. Willd. 23. Vahl. Symb. 3. 26. Pluk. phyt. tab. 167. fig. 3. Feuil. peruv. 3. 16. tab. 11. "Leaves heart-ſhaped, three-lobed; lateral lobes toothed-angular; peduncles, ſomewhat three-flowered; calyxes almoſt as long as the peduncles, ſmooth." Whole plant quite ſmooth, except the petioles. *Stem* cylindrical. *Leaves* two inches long or more, glaucous, green underneath, with purpliſh veins; lobes lanceolate; middle one longer, broader, quite entire, acuminate; lateral ones narrower, attenuated, with a ſmaller broader lobe at the bottom on each ſide, rounded behind, and furniſhed with an angular tooth; petioles ſhorter than the leaf, beſet with a few ſcattered hairs. *Peduncles* ſolitary, ſhorter than the leaf, thickened at the top; lower ones three-flowered; middle ones two-flowered, uppermoſt one-flowered; calyx-leaves oblong, ſomewhat membranous, ending in a briſtle; ſtigma capitate. It differs altogether from C. batatas in the ſmoothneſs of the ſtem, and the form of the leaves. A native of America. 40. C. *acuminatus*. Mart. 94. Willd. 24. Vahl. Symb. 3. 26. "Leaves heart-ſhaped and three-lobed, attenuated; peduncles elongated, many-flowered; calyxes ſmooth." *Stem* with a few minute ſcattered hairs, preſſed cloſe, and viſible only with a magnifier. *Leaves* four inches long, three or more broad at the baſe, three-lobed or entire, quite ſmooth, nerved, acute; lateral lobes lanceolate; middle one egg-ſhaped, attenuated; petioles longer than the leaf. *Flower* large, bell-ſhaped, purple with a pale baſe and five paler rays running to the margin; peduncles axillary, the length of the petioles alternate; pedicels about five, an inch and half long; bractes at the baſe of each pedicel two, lanceolate, attenuated, finely

marmot: in the abdominal pouch of the female, the marſupial bones in both ſexes, and in the ſyſtem of the ſexual organs, with the opoſſum; and in the formation of the poſterior legs, with the kanguroo. The marſupial bones have been alſo obſerved by Geoffroy, in that extraordinary creature, the duck-bill quadruped, *Daſyurus*, the Platypus of Dr. Shaw, and Ornithorhynchus of Geoffroy.

Thus it is evident, the character of an abdominal pouch like that of the opoſſum is not peculiar to this genus of quadrupeds, but common, at leaſt, to three genera of thoſe at preſent known, and we might add from our own obſervations, a circumſtance, not perhaps before noticed, that a ſimilar proviſion exiſts in ſome kinds of fiſhes, as well as in the quadrupeds before mentioned. The exiſtence of this abdominal pouch has furniſhed Vicq d'Azir with the character of a new order of quadrupeds, which he calls *Bourſins*, and of which, according to that author, there are five genera, the opoſſums being divided into two genera, and the kanguroo (Pedimanes), the Platypus (Daſyure), and the new genus Phaſcolome, conſtituting the other three.

Moſt of the true opoſſums inhabit America, and live in holes in woody places, burrowing in the earth, and being of the carnivorous kind, feeding on ſmall birds, poultry, reptiles, worms, and inſects, and alſo on vegetables, eſpecially the ſugar cane. Theſe animals walk indifferently, but they climb trees, by means of their prehenſile tail, with great facility; and are often ſeen ſuſtained by the tail to the branches of trees, watching to ſeize upon ſmall birds when they alight near them. The feet are furniſhed with five toes, the greater one of which is placed remote from the reſt. The abdominal pouch is ſuſtained by means of two bones of a peculiar ſtructure, and which in alluſion to their functions have been called the marſupial bones. The opening of the vagina, which is double, and gave riſe to the name of the genus, from the Greek (didelphis) is moiſtened with a kind of fluid of a yellowiſh colour, and ſo offenſive to the ſmell as to communicate its odour to the whole animal. The fleſh of the opoſſum is, however, occaſionally introduced to table as an article of food.

Species.

MARSUPIALIS. Teats eight, within the pouch. Schreber. *Philander Amboinenſis*, &c. Briſſ.

This ſpecies which inhabits Amboyna, is about the ſize of a large cat. The noſtrils are perpendicular, and lunar; whiſkers long; at each corner of the mouth eight briſtles, and under the throat five: the ears oval, lax, black, with the tip white; the grinders lobate: legs black, ſmooth, and beſet with ſhort hair; and the tail the length of the body.

OPOSSUM. Tail hairy at the baſe: region of the eyebrows paler. *Didelphis Opoſſum*, Gmel. *Semivulpa*, Geſn. *Tlaquatzin*, Hern. *Tai-ibi-Braſilienſibus*, Marcg. *Opoſſum*, Cateſby. *Sarigue*, Buff. *Virginian Opoſſum*, Penn. Shaw's Gen. Zool.

The common or Virginian opoſſum is about the ſize of a ſmall cat. The face is long and ſharp, the mouth wide and armed with very numerous ſharp teeth; the ears thin, naked, blackiſh, round, and ſurrounded with a white border; the legs are ſhort and the feet armed with ſharp claws, but the interior toes or thumbs of the hind feet are flat and rounded, and have nails like thoſe of the monkey tribe. The tail is blackiſh at the origin and covered with longiſh hair; but from that part to the extremity is naked, and covered with a ſcaly ſkin, the diviſions of which are marked in ſuch a manner as to give the tail very much the appearance of a whitiſh ſnake: it is ſtrongly prehenſile, or poſſeſſed of the power of coiling, like thoſe of ſeveral monkies, round any object from which the animal pleaſes to ſuſpend itſelf. Its general colour is a dingy yellow white, with the legs blackiſh, and belly white. The abdominal pouch is a large cavity which can be opened and cloſed at pleaſure. It is in this cavity the teats are ſituated in which the young are placed by the parent immediately after their birth, and where they remain for ſome time after, like fœtuſes deſtitute of hair, and adhering ſtrongly to the teats. When they have attained ſufficient growth and ſtrength they emerge, and afterwards, while they remain young, occaſionally take refuge in the ſame receptacle on the appearance of danger. By this means the opoſſum is enabled to carry away her litter of young with perfect facility and ſafety. This receptacle for the young is common to moſt of the opoſſum tribe, but there are two ſpecies which are deſtitute of it, and have only inſtead a kind of depreſſion or furrow.

This animal is carnivorous and preys on poultry, ſmall birds, &c. in the manner of the European polecat, and alſo feeds on various kinds of fruit. It is of a gentle diſpoſition, and may be eaſily tamed; but, like ſome other ſpecies, has a diſagreable ſmell: its voice is a ſort of grunting ſqueak: its pace in running is not ſwift, but it is very expert in climbing trees, and readily paſſes by means of its clinging tail from bough to bough in the manner of a monkey. The female produces four or five at a birth, and has the power of cloſing the pouch ſo ſtrongly as to make it extremely difficult to open it by the hand; nor will any torture compel the animal to looſen it. This power of ſtrongly cloſing the pouch is performed by certain bones and muſcles which nature has provided for that purpoſe. The female, when ready to produce her young, is ſaid to make herſelf a neſt of dry graſs, in ſome buſh near the root of a tree.—A variety is deſcribed by Gmelin under the name of Molucca, the back of which is dark brown, and the belly whitiſh. This is found chiefly in the iſle of Ceylon.

CAYOPOLLIN. Tail longer than the body: no abdominal pouch: eyes ſurrounded with a black border. Schreber. *Mus Africanus; Cayopollin dictus*. Seba. *Mexican Opoſſum*.

The Cayopollin inhabits the mountainous parts of New Spain where it lives on trees; it has large angular, naked, tranſparent ears, thickiſh ſnout, and large whiſkers. The colour above is browniſh or tawny-aſh, beneath pale grey or whitiſh: the face whitiſh with a dark line down the middle, and a blackiſh or brown border round the eyes. The total length is about ſeventeen inches, of which the body meaſures ſix and the tail eleven.

MURINA. Tail half naked; teats ſix. Linn. *Mus ſylveſtris*, &c. Seba. *Marmoſe*, Buff. *Murine Opoſſum*, Penn.

One of the ſmaller ſpecies of opoſſum, meaſuring ſix or eight inches from the noſe to the baſe of the tail, and having the tail about the ſame length as the body. It is of a ſomewhat ſlender form, with the ſnout long and acute, and the mouth wide; the ears are large and rounded, and the tail naked, or ſcaly throughout its length. This animal has no ventral pouch, but on each ſide the lower part of the abdomen is a longitudinal furrow or fold, in the cavity of which the teats are ſituated. The general colour is tawny brown above, and whitiſh beneath; the eyes encircled with black. It produces ten or more young at a birth, which immediately after being brought forth affix themſelves to the teats, and remain there till they attain their proper growth and ſtrength; it is a native of South America, and particularly of Surinam. The feet in this ſpecies are all furniſhed with ſharp claws, except on the thumbs or great toes of the hind feet, which have rounded nails.

DORSIGERA. Tail at the baſe hairy, and longer than the

the body; toes of the poſterior feet unarmed. Schreber. *Genus gliris ſylveſtris*, Merian. *Philandre de Surinam*, Buff. *Merian opoſſum*, Penn.

This ſpecies, which is deſcribed principally on the authority of madame Merian, is a native of Surinam; it burrows in the ground like the rabbit, and, when in danger, the young are ſaid to affix themſelves to the mother by twiſting their tails round hers. This animal brings forth five or ſix young at a litter, and is about the ſize of the common rat.

Cancrivora. Tail ſcaly, almoſt naked, and nearly as long as the body; thumb of the poſterior feet flat. *Didelphis cancrivora*, Gmel. *Crabier*, Buff. *Cayenne opoſſum*.

A native of Cayenne, firſt deſcribed in the Supplement to the works of Buffon. It is ſaid to be an animal of great activity, living on trees by day, and by night deſcending into marſhy places in order to prey on crabs, which it draws out of their holes by means of its feet, or ſometimes even with its tail. The colour is reddiſh, tawny above, and yellowiſh beneath; the fur ſomewhat woolly, but beſet with coarſer hairs externally, eſpecially along the back, where they form a kind of mane. The face is long and ſlender; the ears upright, ſharp, and pointed; the tail very long, taper, and naked. This animal is about three feet in length, meaſuring from the tip of the noſe to the end of the tail; it grunts like a pig; brings forth from four to five young at a litter, is eaſily tamed, and grows fat by domeſtication. The fleſh reſembles that of the common hare.

Petaurus. Sides furniſhed with a flying membrane: body above blackiſh-grey, beneath white; tail long, ſubcylindrical, and hairy. *Didelphis petaurus, petaurine opoſſum*, Shaw. Gen. Zool. *Hepoona-roo*, White's Journ. *Great flying opoſſum*.

This remarkable ſpecies meaſures about twenty-two inches from the tip of the noſe to the beginning of the tail, which latter is twenty inches in length. The body is about the ſize of a ſmall rabbit, and the general appearance is ſimilar to that of the flying ſquirrel. Its colour is a fine ſable, varied with a greyiſh ferruginous caſt above, the lower ſurface whitiſh; a ſtripe of deep brown runs along the back from head to tail, and the verge of the flying membrane on the upper part has a darker tinge than the reſt, while the extreme edge is white. The tail is very full of long, and ſoft hairs of a blacker caſt than the reſt, eſpecially towards the end. This ſingular animal is enabled, by means of its expanſile lateral membranes, to ſpring to a conſiderable diſtance at pleaſure; it inhabits New Holland, where the natives diſtinguiſh it by the name of Hepoona-roo.

Lemurina. Cinereous, beneath tawny; tail cylindrical, black, furry, and prehenſile. *Didelphis lemurina, lemurine opoſſum*, Shaw Gen. Zool. *Wha-tapoa-roo*, White's Journ.

A large ſpecies, being equal in ſize to the common cat, but of a more elongated form in proportion. The upper part is an iron-grey, beneath tawny, more or leſs pale. The muzzle is ſhort and roundiſh; whiſkers large and black, the ears upright, large, and rather acuminated at the top; its eyes are bright and reddiſh. The poſterior feet furniſhed with a rounded interior toe. The tail, which is very thick, long, and furry, is prehenſile, and for about a fourth part of its length of the ſame colour with the body, the remainder black; the tail is naked beneath to a conſiderable diſtance from the tip. The total length of this animal is about two feet ſix inches, of which the tail alone meaſures about twelve inches.

This kind, like moſt others of the genus, ſubſiſt on ſmall birds, inſects, and vegetables, and when they feed are obſerved to ſit upright in the ſame manner as the ſquirrel.

Obesula. Pale brown; beneath whitiſh; tail rather long. *Didelphis obeſula, porculine opoſſum*, Shaw. Nat. Miſ.

About the ſize of a half grown domeſtic rat; the hind legs are conſiderably longer than the others, and ſomewhat reſemble thoſe of the kanguroo; the ears are rounded, the tail rather long, and its hair more coarſe in appearance than in the reſt of the ſmall opoſſums.

Viverrina. Black ſpotted with white; tail hairy. *Didelphis viverrina, viverrine opoſſum*, Shaw. Gen. Zool.

This animal is remarkable for its ſlender form, and in its general figure bears a ſtrong reſemblance to the weeſel tribe. The colour is deep gloſſy black, and the whole body and outſides of the limbs are marked with numerous, large, and ſomewhat irregular patches of white. Mr. Hunter ſpeaks of a variety which is entirely brown and immaculate.

Philander. Tail hairy at the baſe; abdominal pouch with four teats. Schreber. *Tlaquatzin*, Seba.

The philander is about the ſize of a large rat; the head large, the ſnout thick, and the ears rounded and erect. The tail is longer than the body, and is hairy at the baſe, the reſt naked. The length of the body is nine inches, and the tail thirteen. The general colour of this animal is reddiſh brown above, beneath whitiſh; the eyes are ſurrounded with a browniſh border; and the mouth beſet on each ſide with whiſkers. The forehead is marked with a browniſh ſtripe. This ſpecies inhabits Surinam.

Orientalis. Tail hairy from the baſe to the middle, and longer than the body; two middle toes of the poſterior feet united. Pallas. *Phalanger*, Buff.

The phalanger is the ſize of a very large rat, meaſuring about nine inches from the noſe to the tail, and the tail itſelf ten inches. The colour of the phalanger is rufous grey on the upper part, and yellowiſh white beneath; the top of the head, and the back marked with a blackiſh line; the tail is hairy for about two inches and a half from the baſe. Its voice is ſaid to reſemble that of the ſquirrel, and it commonly aſſumes the attitude of that animal when feeding.

Brunii. Tail ſhort, naked; poſterior feet long and tridactylous. Schreber. *Filander*, Le Bruyn. *Javan opoſſum*, Penn.

This ſpecies, which is about the ſize of the common hare, was firſt diſcovered by Le Bruyn in the iſland of Java. The head is narrow, and ſhaped like that of the fox, with the ears placed erect. The general colour of the animal is pale yellowiſh brown, with a brown ſtripe along the forehead. The abdominal pouch is large. Bruyn refers this animal to the kanguroo tribe.

Brachyura. Tail hairy, and very ſhort; ears naked; no pouch; body rufous. Schreber. *Short-tailed opoſſum*, Penn.

One of the ſmaller ſpecies ſeldom exceeding the length of five inches from the noſe to the tail, and the latter about two inches. Its colour is a reddiſh brown on the upper parts, and whitiſh beneath. This ſpecies being deſtitute of an abdominal pouch, the young faſten themſelves to the teats. The fur of this animal is ſoft and elegant, the tail very thick at the baſe, and gradually tapering to the end. It is a native of South America.

Sciurea. Sides furniſhed with a flying membrane; body above greyiſh, beneath ſnowy white; tail prehenſile and very hairy. *Didelphis ſciurea, ſquirrel opoſſum*. Shaw Zool. New Holl.

The ſize of this animal is nearly that of the common European ſquirrel, and from the fullneſs and peculiar growth of its hair, appears rather larger. Its general colour reſembles that of the American grey ſquirrel. A black ſtripe paſſes over each eye along the top of the head; and under

each

each ear is a black patch ſurrounded with white. The tail, which is prehenſile, is of the ſame colour with the body for half its length, but the remainder is black; it is remarkably full of hair, and tapers in a ſlight degree towards its extremity, but does not terminate acutely. The eyes are black, rounded, and very full; the ears rather ſhort, round, and very thin. The upper parts of the feet are white, and the lateral or flying membrane, which extends from the fore feet to the hind, is edged with blackiſh, as in the flying ſquirrels. The abdominal pouch is of conſiderable ſize, and is ſituated, as in other opoſſums, on the lower part of the abdomen. The poſterior feet are furniſhed with a rounded unarmed thumb. This curious animal is of the nocturnal kind, remaining during the greateſt part of the day in a ſtate of torpidity, but appearing in the night time full of vigour and activity. This ſpecies inhabits New Holland.

Dr. Shaw ſpeaks of a ſuppoſed variety which agrees in every reſpect with that above deſcribed, except in having the extreme half of the tail black, that part being nearly throughout of the ſame grey colour with the upper ſurface of the animal, and only marked near the end with a black band; the tip is white.

Macroura. Sides furniſhed with a flying membrane; body cinereous above, beneath white; tail very long and black. *Didelphis macroura, long-tailed opoſſum.* Shaw Zool. New Holl.

This ſpecies is about the ſize of a black rat, and is of a dark or browniſh grey above, the lower ſurface white; the head and neck are alſo whitiſh; a duſky ſtripe runs along the top of the head, almoſt to the noſe; the ears are whitiſh, moderately large, and ſlightly rounded; the upper parts of the fore feet are whitiſh, and the poſterior half of the tail deeper black than the other part. Native of New Holland.

Pygmæa. Sides furniſhed with a flying membrane; tail flat, pinnated, and linear. *Didelphis pygmæa, pigmy opoſſum.* Shaw Zool. New Holl.

The moſt diminutive of the opoſſum tribe, its ſize being equal only to that of the common mouſe. This elegant little animal is furniſhed on each ſide the body with an expanſile membrane, like that of the flying ſquirrel, and by the aſſiſtance of which it is enabled to ſpring to a conſiderable diſtance. The fur is extremely fine; its colour a ſoft and paliſh brown above, beneath almoſt white; the noſe, feet, and ears, internally, are light pink. The tail is of a flattened form, and beautifully fringed on each ſide with ſoft, ſilky hairs. The opening of the abdominal pouch is of a ſemilunar form. The teats are extremely ſmall, and only four in number. Its tongue is remarkably large and long, and of a flattened form. The ſpecies is ſuppoſed to feed chiefly on inſects and young birds.

Pencillata. Cinereous, beneath whitiſh; tail at the end hairy and black. *Didelphis pencillata, bruſh-tailed opoſſum* Shaw Gen. Zool.

The prevailing colour of this ſpecies is cinereous, or deep grey; the noſe is rather ſharp; the ears moderately large, and of a very ſlightly pointed form at the tips; the ſides of the mouth are furniſhed with very long fine briſtles; and others, ſomewhat ſhorter, are ſituated under each eye. The ſides are dilated into a flying membrane. The tail is thin and aſh-coloured for nearly half its length, beyond which it is jet black, with long and fine hairs diſpoſed in a bruſh like form. Its ſize is that of the black rat. Native of Auſtralaſia.

Vulpina. Ferruginous; tail hairy and black. *Didelphis vulpina, vulpine opoſſum.* Phillip's Voy. New South Wales.

This is one of the larger ſpecies of opoſſum, meaſuring about twenty-ſix inches from the noſe to the baſe of the tail, and the tail itſelf being fifteen inches in length. The general colour is duſky grey, with a rufous tinge above, and being tawny buff colour, deepeſt on the throat. The tail is of the ſame colour with the back for about one-fourth of its length, and from thence to the end black. It is conjectured that this may in reality be no other than the lemurine opoſſum, *Didelphis lemurina.*

Ursina. Yellowiſh, with the upper lip bifid. Shaw Gen. Zool.

A ſpecies of large ſize very lately diſcovered in New Holland.

It ſhould be laſtly obſerved, that Gmelin includes the kanguroo in the didelphis genus, under the ſpecific name of *gigantea*, a circumſtance that muſt have ariſen from inattention to the ſtructure and arrangement of the teeth and other eſſential characters, which at once remove that ſingular animal from the didelphis tribe. See Kanguroo.

DIDELTA, in *Botany*, (from δις, *double*, and δελτα, the Greek letter Δ, in alluſion to the form of the fructifying diſk, which reſembles one equilateral triangle within another;) L'herit. Stirp. t. 28. Ait. Hort. Kew. v. 3. 256. Schreb. 590. Willd. Sp. Pl. v. 3. 2262. Juſſ. 182. Lamarck t. 705. Claſs and order, *Syngeneſia polygamia-fruſtranea.* Nat. Ord. *Corymbiferæ, Sect.* 2. Juſſ.

Gen. Ch. *Cal.* the common one double: outermoſt in three deep, ovate, widely-ſpreading ſegments; inner in 11 or 12 unequal, linear-lanceolate, pointed, ſpreading ſegments, alternately ſmaller. *Cor.* compound, radiated: florets of the diſk hermaphrodite in ſtructure, numerous, funnel-ſhaped, five-cleft; thoſe in the central triangle in effect barren, the ſurrounding ones fertile: florets of the radius 11 or 12, female, but abortive, ligulate, with three or four teeth, longer than the calyx, and oppoſite to its twelve internal ſegments. *Stam.* Five in all the florets of the diſk; filaments capillary, very ſhort; anthers united into a tube: in thoſe of the radius ſolitary and obſolete. *Piſt.* Germen in the external florets of the diſk oblong, compreſſed, immerſed in the receptacle; ſtyle thread-ſhaped; ſtigma cloven, revolute: in the central ones the germen is minute and roundiſh: in the marginal ligulate florets is ſcarcely the rudiment of any. *Peric.* None. *Receptacle* ſplitting into three portions, each of which has one large ſegment of the calyx, and ſome of the ſmaller inner ones, adhering to it, and contains ſeveral ſeeds in its cells. *Seeds* none, either in the central or radiant florets; in the external florets of the diſk oblong; down ſhort, ſimple, rigid. The common receptacle is triangular, divided into four triangular parts, of which the central one is naked, the reſt fungous and briſtly. Eſſ. Ch. Receptacle briſtly, triangular; its centre triangular and barren. Down of many ſcales. Outer calyx in three deep ſegments; inner in many. 1. D. *carnoſa.* Ait. Hort. Kew. v. 3. 256. Willd. Sp. Pl. v. 3. 2262. (D. tetragoniæfolia; L'herit. Stirp. Nov. 55. t. 28. Polymnia carnoſa; Linn. Suppl. 384. Choriſtea carnoſa; Thunb. Prod. 163.) Succulent-leaved Didelta. "Leaves alternate, lanceolate-oblong, fleſhy." Grows at the Cape of Good Hope in ſandy ground. It was ſent to Kew garden in 1774, by Mr. Maſſon, and is kept in the green-houſe, flowering in July. Stem ſhrubby, branched, angular, ſpreading. Leaves from an inch to two inches long, thick and juicy, entire, obtuſe, ſomewhat downy beneath. Flowers on long, ſimple, ſolitary, terminal ſtalks, large and handſome, yellow or orange. Calyx with prickly teeth. 2. D. *ſpinoſa.* Ait. Hort. Kew. v. 3. 256. Willd. Sp. Pl. v. 3. 2262. (Polymnia ſpinoſa; Linn. Suppl. 384. Choriſtea ſpinoſa; Thunb. Prod. 163.) Oppoſite-leaved Didelta. "Leaves oppoſite, ovate, half claſping the ſtem." Found at the Cape of Good Hope, by Thunberg

Thunberg and Maſſon, the latter of whom ſent it to Kew, in 1774. It flowers in June and July, and requires the ſhelter of a green-houſe. Hort. Kew. "Stem ſhrubby, erect. Leave broad-ovate ſomewhat heart-ſhaped, ſmooth, with prickles above their inſertion. Calyx entire; the outermoſt of 5 leaves or ſegments." Linn.

DIDEROT, Denys, in *Biography*, an eminent French writer, was ſon of a cutler at Langres, where he was born in 1713. He was educated among the Jeſuits, who, finding him a youth of excellent talents, were very deſirous of retaining him in their ſociety, but he was ill inclined to adopt the eccleſiaſtical profeſſion, and his father ſent him to Paris to finiſh his ſtudies, intending to bring him up to the buſineſs of the law. Literature, however, was his delight, and ſo intent was he in improving his mind, that he neglected the duties of his ſituation. His father was offended at his conduct, and refuſed, for ſome time, to continue his uſual ſupport. But he had a mind calculated to riſe above trifling obſtacles, and continued his ſtudies in phyſics, geometry, and metaphyſics; in theſe and in the belles lettres he made very conſiderable progreſs. When he was about thirty years of age he commenced author, and one of his earlieſt publications was a tranſlation of "Stanyan's Hiſtory of Greece" from the Engliſh. In 1745, he publiſhed a ſmall work, entitled "Principles of Moral Philoſophy," and in the following ſpring he publiſhed his "Penſées Philoſophiques," by which he obtained conſiderable celebrity. From this period he was received as a diſciple of the new philoſophy; and became at length one of its ableſt advocates. He republiſhed his "Penſées" under the title of "Etrennes aux Eſprits forts," when it was very generally circulated, and contributed much to the prevalence of thoſe opinions for which France has the laſt half century been diſtinguiſhed. It was at this period that Diderot, in conjuncture with d'Alembert, laid the foundation of the "Dictionaire Encyclopedique," which was intended not only as a magazine of every ſpecies of human knowledge, but as an engine to ſubvert all eſtabliſhed opinions. The firſt edition of this work was publiſhed between the years 1751 and 1767, in 28 vols. folio. To this, as editor, Diderot gave the labour of almoſt twenty years, but allowing himſelf time for the publication of many ſeparate works; of which, ſome have done credit to his talents, and others, particularly his "Bijoux Indiſcreets," have injured his reputation, and have been highly injurious to the morals of his countrymen. His writings have been characterized, and juſtly, as "containing a glaring mixture of good and bad, of brilliant thoughts, and obſcure reaſoning; of ſentences that dart from the imagination with the energy of lightning; and cloudy periods of metaphyſical rhetoric, that convey either no ideas, or falſe ones. This great dictionary, though very popular, did not remunerate the editors for the time and labour which it occupied. Diderot was obliged, when it was finiſhed, to ſell his library; he fortunately met with a liberal purchaſer in the empreſs of Ruſſia, who paid him 50,000 livres for it, and left him the uſe of it during life. She and the great Frederic were the avowed diſciples of the French ſchool. This able writer on mathematics, mechanics, arts, and manufactures, all which he had explored, extended his inquiries and reflections to muſic: and while M. Bemetzrieder, a diſciple of Schobert, was teaching his daughter on the piano-forte, M. Diderot contrived generally to be preſent at the lecture, and drew up, in dialogues between maſter and ſcholar, the moſt pleaſing and clear elementary treatiſe on the principles of muſic, and the art of performing on that inſtrument, which has perhaps ever been printed in any language.

The dialogue is as lively as in the beſt written comedies. Among his miſcellaneous works there is an excellent eſſay on acouſtics. His knowledge, perſeverance, and acquirements, ſeem to have been unlimited.

He, d'Alembert, the abbé Arnauld, and M. Suard, were among the firſt in France to feel the ſuperior merit of Italian muſic, over the old French ſtyle of Lulli and Rameau, which contributed much to its diſgrace whenever an opportunity offered for a parallel. Unfortunately, Diderot was as confirmed a philoſopher as Voltaire, which, when generally known, cauſed the doors of almoſt all the great academies in Europe to be ſhut againſt him, and prejudiced the friends of religion againſt his other writings, however excellent. During the muſical reform that was attempting in France, he made remarks and reflections on the ſubject, ſufficient to fill a 4to. vol. which ſtill remains in manuſcript, and in the hands of the writer of this article, to whom he preſented them more than thirty years ago, but little uſe has been made of theſe remarks hitherto; yet in the courſe of drawing up the muſical articles for the preſent Cyclopædia, they will not be forgotten. Diderot died ſuddenly, as he was riſing from table, in July, 1784.

DIDIER, Saint, in *Geography*, a ſmall town of France, in the department of the Rhone, 3 miles from Lyons; alſo a ſmall town of France, in the department of the Loire, not far from St. Etienne.

Didier, *Saint, et la Séauve*, a ſmall town of France, in the department of the Upper Loire, diſtrict of Yſſengeaux, chief place of a canton, with a population of 3175 individuals. The canton has 7 communes, and 10,458 inhabitants, upon a territorial extent of 152½ kiliometres.

DIDIUS Julianus, *M. Salvius Severus*, in *Biography*, a Roman emperor, who, in early life, had been employed in public ſtations, and who, A. D. 179, was made conſul with Pertinax. In the reign of Commodus he was accuſed of ſome ſtate offences, of which he was acquitted; but whether on account of his innocence, or by means of his wealth, does not appear. At that period of the empire almoſt every thing was attainable by riches. Julian had accumulated a prodigious ſum, to which he owed his elevation to the throne. When Pertinax was dethroned and murdered, the ſoldiers reſolved that the crown ſhould be transferred to the higheſt bidder. The news quickly ſpread over the city, and reached the ears of Didius Julianus, who, regardleſs of the public calamities, was indulging himſelf in all the luxuries that his wealth could command. His wife and his daughters, his freedmen and his paraſites, eaſily convinced him that he deſerved the throne, and conjured him to embrace the favourable opportunity. He immediately repaired to the camp, where Sulpicianus had already began to bargain with the ſoldiers. Didius in an inſtant made a large advance upon his offer, and raiſed the bribe to 200*l.* ſterling *per* man. The gates of the camp were inſtantly thrown open to the purchaſer; he was declared emperor, and received the oath of allegiance from the ſoldiers, who retained ſo much humanity as to ſtipulate that he ſhould pardon and forget the competition of Sulpicianus. The Prætorians placed their new ſovereign in the centre of their ranks, ſurrounded him on every ſide with their ſhields, and conducted him in cloſe order of battle through the deſerted ſtreets of the city. The ſenate was commanded to aſſemble, who, through fear, ratified the infamous tranſactions. They congratulated their own, and the public felicity; engaged their allegiance, and conferred on the new emperor all the branches of imperial power. He was next conducted to the palace, where he beheld the abandoned trunk of Pertinax, and the frugal entertainment that had been prepared for his ſupper. The one he viewed with apparent indifference, the other with contempt. A banquet was prepared by his order, and he amuſed himſelf till a late hour, with dice, and the performances of a celebrated dancer.

dancer. It was obſerved, that when left to darkneſs, ſolitude and himſelf, he paſſed a ſleepleſs night, reflecting on the dangerous tenure of an empire that had not been acquired by merit, but purchaſed by money. "He had," ſays the eloquent hiſtorian, "reaſon to tremble. On the throne of the world he found himſelf without a friend, and even without an adherent. The guards themſelves were aſhamed of the prince whom their avarice had perſuaded them to accept, nor was there a citizen who did not conſider his elevation with horror, as the laſt inſult of the Roman name." The people refuſed the proffered liberality of the emperor; inſulted his perſon, and waited with anxiety for the armies in the diſtant provinces, as avengers of the public wrongs. The approach of Severus, who had been declared emperor by the Pannonian legions, ſoon brought on the criſis of his fate. He was deteſted by the Prætorians; was formally depoſed, and ſentenced to death. He met with no compaſſion, but ended, like a common malefactor, his wretched reign of ſixty-ſix days, at the age of ſixty. Gibbon.

DIDO, in *Fabulous Hiſtory* and *Mythology*, the ſurname of the princeſs Eliſa, who is ſaid to have founded Carthage. She was the daughter of Belus II. king of Tyre, in Phœnicia. When her brother Pygmalion aſcended the throne after the death of his father, and Eliſa was married to Sicharbas, the prieſt of Hercules, his mother's brother, who was immenſely rich; the dread of Pygmalion's avarice induced them to keep ſecret this great wealth. Pygmalion, however, conjecturing that that was the caſe, cruelly murdered the huſband of his ſiſter. Eliſa, diſſembling her reſentment, and profeſſing her deſire to leave a place where her grief was renewed, took up her abode with Pygmalion. The king, preſuming that ſhe would bring with her the treaſure of her huſband, ſent her a ſhip and convoy; but before ſhe ſet ſail, ſhe artfully contrived to lodge in the ſhip ſome bales loaded with ſand; and having reported that ſhe was going to ſacrifice to the manes of her huſband what ſhe chiefly valued, ſhe took an opportunity of throwing theſe bales into the ſea; and then told the ſoldiers, who accompanied her, that they contained the money of Sicharbas, and that they had no alternative for their own ſafety but that of flying with her; for as ſoon as Pygmalion found that they were come without the expected treaſure, he would put them all to death. Accordingly they firſt landed in Cyprus, whence Dido carried off 50 young virgins, whom ſhe gave in marriage to the companions of her expedition. They were afterwards driven by the winds on the coaſt of Africa, where this princeſs erected a citadel, near which Carthage was afterwards built. It has been ſaid by fabulous tradition, that Dido bought of the inhabitants of the country as much ground as a bull's hide would encloſe; and that ſhe cut this into a great number of thongs, which encompaſſed a ſpace of ground ſufficient for the ſite of a citadel, which was hence called *Byrſa*, *i. e.* a bull's hide; and it has been farther ſaid, that in digging the foundation, they found a horſe's head, which preſaged its future grandeur. See CARTHAGE.

After the Phœnicians, whom Dido led into this part of Africa, had made their ſettlement there, they attempted to compel the princeſs to marry Iarbas, king of Mauritania: but ſhe diſappointed their views, by firſt erecting a funeral pile, as if by ſome ſacrifice ſhe intended to appeaſe the manes of her former huſband, and afterwards putting an end to her life with a poniard. From this action, it is ſaid, ſhe obtained the name of Dido, importing *valiant woman*: but Virgil, by a ſtrange reverſe of hiſtory, repreſents her as being ſo much in love with Æneas, that his departure drove her to deſpair. But it is remarkable, that he makes an anachroniſm of almoſt 300 years, as there is no leſs an interval between Æneas and Dido; for, notwithſtanding a variety of opinions about the time in which ſhe lived, it is generally agreed that it was later than that of the Trojan heroes by ſome ages: Troy having been taken in the time of the judges, and Pygmalion, Dido's brother, having been born in the reign of Joram, king of Judah, about 889 years B.C. Accordingly Bochart makes Dido to have been aunt to the famous Jezebel, whom Ahaz married, and who brought ſo many calamities upon the kingdom of Iſrael. Moreover, Dido left the kingdom of Tyre in the 7th year of Pygmalion's reign, about 300 years after the taking of Troy, and between eight and nine hundred years B. C. After her death her ſubjects aſcribed to her divine honours and paid her religious worſhip. Sir Iſaac Newton, in his Chronology, repreſents Æneas and Dido as contemporaries in the year 883, B. C.; when, as he ſays, Dido built Carthage, and he ſtates the capture of Troy to have happened in the year 904 B.C., which others refer to 1184 B. C.

DIDRACHM, from δις, *double*, and δραχμα. See DRACHM.

DIDUGUA, in *Ancient Geography*, a town of Aſia, in Babylonia.

DIDURI, a people of Aſiatic Iberia, according to Pliny. Ptolemy places them in Sarmatia, in the vicinity of the Caſpian ſea.

DIDUS, in *Ornithology*, a genus of the gallinaceous tribe. The bill is ſtraightened in the middle with two tranſverſe wrinkles, and both mandibles are bent in at the tip; the noſtrils are placed obliquely near the edge of the middle of the bill; face naked beyond the eyes; legs ſhort, thick; feet cleft; wings unfit for flight. DODO.

Species.

INEPTUS. Greyiſh; wings and tail cinereous yellow; head hooded. *Didus ineptus*, Linn. *Raphus*, Briſ. *Cygnus cucullatus*, Raii. *Hooded Dodo*, Lath. Edw. &c.

The exiſtence of this uncouth bird has been diſputed, though not in our opinion with ſufficient reaſon, for although this curious creature has not been ſeen by any modern traveller, or naturaliſt, the evidence of thoſe reſpectable authors who deſcribed it in the early part of the 17th century, ought not to be rejected. The Dutch are ſaid to have found it in the iſle of Mauritius, and to have given it the name of Dodaerts, and Walgh-vogel; the name Dodo is that by which the Portugueſe diſtinguiſhed it, and the French called it Cygne à capuchon, and autruche encapuchonnée, but the name under which it was firſt noticed by them is Dronte.

In Herbert's travels, publiſhed in 1634, an account of this bird is inſerted, accompanied by a rude and indifferent figure, under the name of Dod-eerſen. He informs us that "it ſeldom weighs leſs than fifty pounds. The bill is hooked and bent downwards; the thrill, or breathing-places in the midſt; from which part, to the end, the colour is of a light-green, mixed with pale yellow; eyes round and bright; has fine down inſtead of feathers; the train (like to a China-beard) is no more than three or four ſhort feathers; the head variouſly dreſſed, one-half being hooded with down of a dark colour, the other half naked, and of a white hue, as if lawn were drawn over it; the legs thick and black, and the talons great. The pace, he ſays, is ſlow, and the body round and fat; by ſome eaten as meat, but more pleaſureable to look than feed upon, and her ſtomach ſo fiery that it can eaſily digeſt ſtones; in that ſhape not a little reſembling the oſtrich." A painting of this bird is preſerved in the Britiſh muſeum, to which Edwards is indebted for the following deſcription, and from which alſo the various figures of the Dodo, in that, and later publications, are evidently copied.

According to Edwards, this bird is rather larger than the ſwan, and nearly three feet in length. The bill is ſtrong, large, and hooked at the end; the gape ſtretches beyond the eyes, and is of a pale blue colour, except the end of the upper mandible, which is yellowiſh, and a red ſpot on the bend of it; the end of the lower blackiſh; irides white; the general colour of the plumage cinereous, and ſoft to the touch; the belly and thighs whitiſh; the head large, and ſeems as it were covered with a black hood or cowl; the wings are very ſhort, and of a yellowiſh aſh-colour; the tail-feathers curled, ſtand upon the rump, and incline to yellow, like the wings; the legs have four toes, three before, and one behind, and are very ſtout, ſhort, and yellowiſh, and armed with black claws.

Gmelin affirms that the didus or dodo family has no tail; the caudal feathers are certainly not placed at the extremity of the body as in other birds, but conſiderably higher upon the back, and aſſuredly from their ſituation rather deſerve the epithet of a dorſal tuft than tail. The ſame writer obſerves alſo that the hooded dodo has no claws or toe-nails: upon what authority this writer ſpeaks we cannot preſume to determine, but the ſame aſſertion has been ſince made by Sonnini. We are aware that an opinion did prevail to this effect, till the recent diſcovery made in the Britiſh Muſeum, of the legs of a large bird, conjectured to be thoſe of the hooded dodo, and which appear, at leaſt for the preſent, to diſcountenance that idea, the toe-nails in thoſe relics being not only viſible but very conſpicuous.

Solitarius. Varied grey and brown; wings ſhort and terminating in a rounded knob. Lath. *Didus Solitarius*, Gmel. —*Le Solitaire*, Buff.—Solitary Dodo.

Nearly as large as the former. This ſpecies is an inhabitant of the iſle of Rodrigue, where it is not uncommon, but never appears in large flocks, ſcarcely more than two being ever found together: it makes its neſt in retired places of the leaves of the palm, about eighteen inches in thickneſs, and lays one egg, which is larger than that of the gooſe. The male ſits in his turn, or ſtands on the watch, and will not ſuffer any bird to approach within a moderate diſtance of the neſt while the hen is ſitting, which continues for ſeven weeks. They are chaſed in the winter ſeaſon between March and September, being then very fat, and the young birds in particular much eſteemed at that time for the table.

This bird bears ſome reſemblance to the turkey; the legs are as in that bird, but longer, and the bill is more bent in proportion. The neck is of a proportionable length, and the eyes black and lively: the general colour of the plumage is grey and brown mixed, and it has ſcarcely any tail: the wings are too ſhort for flight, and the hind parts are rounded like a horſe's rump, and clothed with feathers. The females are ſometimes covered with brown and light yellow feathers, and appear very beautiful. This ſex has a kind of widow's peak above the bill; and the feathers on each ſide enlarge into two white tufts: the feathers of the thighs are rounded at the end like ſhells, and this conſtitutes the principal character of the ſpecies.

Nazarenus. Body entirely downy and black. Lath. —*Didus nazarenus*, Gmel.—*Oiſeau de Nazareth*, Buff.—Nazarine Dodo.

This is rather larger than the ſwan: the bill is a little bent downwards and large; and inſtead of feathers the whole body is covered with a black down: the wings conſiſt of feathers, and there are ſome frizzled feathers upon the rump which ſupply the place of a tail: the legs are long and ſcaly, and, unlike the two former birds, there are only three toes on each foot inſtead of four.

The ſpecies was met with in the iſle of France, and is deſcribed by Caiſche a French writer. This bird forms its neſt of leaves and dry herbs in the foreſts on the ground, and lays only a ſingle egg, which is large and white.

DIDWANA, in *Geography*, a town of Hindooſtan, in the country of Agimere; 30 miles N. E. of Nagore, and 51 N. of Agimere.

DILYMA, a fountain of Greece, in Theſſaly.—Alſo, two ſmall iſlands; near that of Scyros.—Alſo, one of the Æolian iſles near Sicily.—Alſo, a town of Africa in Libya.

DIDYMÆUS, in *Mythology*, an appellation given to Apollo.

DIDYMANDRA, in *Botany*, (from διδυμος, *a twin*, and ανηρ, *a man*, in alluſion to the two anthers upon one filament.) Willd. Sp. Pl. v. 4. 971. (Synzyganthera, Ruiz. and Pavon. Prodr. 137. t. 30.) Claſs and order, *Polygamia Monœcia*; Willd. Nat. Ord. *Amentaceæ*.

Eſſ. Ch. Catkin cylindrical, with imbricated ſcales, bearing united as well as female flowers.

United Fl. Cal. deeply four-cleft. Cor. deeply four-cleft. Filament ſolitary, bearing two anthers at its ſummit. Germen ſuperior. Styles three, very ſhort. Berry with three cells. and three ſeeds.

Female, Cal. and Cor. with Styles and Berry as in the former.

1. D. *purpurea*. Willd. (Synzyganthera purpurea; Ruiz. and Pavon. Syſt. Veg. Fl. Peruv. v. 1. 273.) A native of umbrageous woods in Peru. The tree is ſaid by the Spaniſh botaniſts to be near forty feet high, with oblong-lanceolate pointed leaves. From them Willdenow has adopted the above characters, very properly changing their uncouth name, as it had not as yet found its way into any book in common uſe.

DIDYMELES, (from διδυμος, *a twin*, and μηλις, *an apple*, becauſe, as we preſume, the fruit grows in pairs.) Aubert Hiſt. Inſ. Afr. 23. t. 3. Willd. Sp. Pl. v. 4. 648. Claſs and order, *Diœcia Monandria*. Nat. Ord. *Amentaceæ*?

Eſſ. Ch. Male, Flowers in pairs, joined at the baſe. Cal. a ſcale. Cor. none. Anther ſeſſile.

Female, Fl. in pairs, joined at the baſe. Cal. a ſcale. Cor. none. Style none. Stigma of two lobes. Drupa with one ſeed.

1. D. *madagaſcarenſis*. Willd. loc. cit.

"A tall tree, found in Madagaſcar. The leaves are alternate, ſtalked, oblong, tapering at the baſe, entire, veiny. Male flowers panicled, female ones ſpiked. Flowers always in pairs." Willd.

DIDYMI, Διδυμοι, the ſame with *gemelli*, or *twins*.

Didymi, in *Ancient Geography*, mountains of Greece, in Theſſaly.—Alſo, a gulf of the iſle of Crete.

DIDYMODON, in *Botany*, an Hedwigian genus of moſſes, the teeth of whoſe fringe are approximated in pairs. It is referred by Dr. Smith to *Trichoſtomum*, which ſee.

DIDYMOTICHOS, in *Ancient Geography*, a ſmall town of Thrace, near the river Hebrus.—Alſo, a place of Aſia Minor, in Caria.

DIDYMUS, in *Biography*, a grammarian of Alexandria, who flouriſhed in the age of Auguſtus, and who is celebrated for having compoſed nearly four thouſand books, none of which have come down to us. Seneca ſpeaks of the ſubjects which Didymus diſcuſſed as trifling in themſelves, or, as he ſays, ſubjects which are forgotten, or which ought to be forgotten if they were known.

Didymus, of Alexandria, preſident of the catechetical ſchool in that city, flouriſhed in the fourth century. When he was but four years old he loſt his ſight, yet ſo vigorous and intenſe was his application, that he became deeply learned in many branches of ſcience. As he advanced in life he diligently ſtudied the ſcriptures of the Old and New Teſtament, on which he wrote ſeveral judicious and learned com-

mentaries, and ſo converſant was he in controverſial theology and eccleſiaſtical hiſtory, that, from his ſuperior merit only, he was elected to fill the chair of the Alexandrian ſchool. St Jerome and other celebrated characters were among his ſcholars, who never loſt an opportunity of ſpeaking loudly of the pre-eminence and learning of their maſter. Jerome pronounced him to be the moſt learned man of the age, and Palladius affirms that he ſurpaſſed all the ancients in the extent and variety of his knowledge. He was author of many learned works, of which one only has reached us; *viz.* "A Treatiſe on the Holy Spirit," tranſlated into Latin by his ſcholar, St. Jerome, and inſerted among the works of that father.—Moreri. Lardner.

Didymus, an eminent muſician of Alexandria, and, according to Suidas, cotemporary with the emperor Nero, by whom he was much honoured and eſteemed. This proves him to have been younger than Ariſtoxenus, and more ancient than Ptolemy, though ſome have imagined him to have preceded Ariſtoxenus. He wrote upon grammar and medicine, as well as muſic; but his works are all loſt, and every thing we know at preſent of his harmonical doctrines is from Ptolemy, who, by diſputing, preſerved them. However, this author confeſſes him to have been well verſed in the canon and harmonic diviſions, and if we may judge from the teſtimony even of his antagoniſt, he muſt have been not only an able theoriſt in muſic, but a man of conſiderable learning. As this muſician preceded Ptolemy, and was the firſt who introduced the minor tone into the ſcale, and, conſequently, the practical major 3d $\frac{4}{5}$, which harmonized the whole ſyſtem, and pointed out the road to counterpoint, an honour that moſt critics have beſtowed on Ptolemy, he ſeems to have a better title to the invention of modern harmony, or muſic in parts, than Guido, who appears to have adhered, both in theory and practice, to the old diviſion of the ſcale into major tones and limmas.

"The beſt ſpecies of diapaſon," ſays Doni, "and that which is the moſt replete with fine harmony, and chiefly in uſe at preſent, was invented by Didymus. His method was this: after the major ſemitone E F $\frac{16}{15}$, he placed the minor tone in the ratio of $\frac{10}{9}$, between F G, and afterwards the major tone $\frac{8}{9}$ between G A; but Ptolemy, for the ſake of innovation, placed the major tone where Didymus placed the minor." Ptolemy, however, in ſpeaking of Didymus and his arrangement, objects to it as contrary to the judgment of the ear, which requires the major tone below the minor. The ear certainly determines ſo with us: is it not therefore probable, that in Ptolemy's time the major key was gaining ground? Upon the whole, however, it appears, that theſe authors only differ in the order, not the quality of intervals.

Didymus, in *Ancient Geography*, a mountain of Aſia Minor, named *Dindyma* by Steph. Byz. Herodotus places here the ſource of the river Hermus.

Didymus, or *Didymi*, mountains of Arabia Felix, in the country of the Sachalites. Ptolemy.

DIDYNAMIA, in *Botany*, (from δις, and δυναμις, *power*, implying the ſuperiority of two ſtamens over the reſt,) the 14th claſs of the Linnæan artificial ſyſtem, but which is in itſelf a natural claſs, or nearly ſo, comprehending almoſt all the ringent and perſonate flowers. Its character conſiſts in having four ſtamens, two of which are longer than the other two. The natural character of the flowers is as follows. *Cal.* Perianth of one leaf, erect, tubular, permanent, five-cleft, more or leſs irregular or unequal. *Cor.* of one petal, erect, irregular, its tube ſecreting or containing honey; its limb uſually two-lipped and ringent. *Stam.* Filaments four, linear, parallel, inſerted into the tube, moſtly curved, according to the direction of the upper lip, ſometimes divaricated as they fade; anthers cohering in pairs, moſtly overſhadowed by the upper lip. *Piſt.* Germen almoſt always ſuperior; ſtyle ſimple, except in *Perilla*, thread-ſhaped, parallel to and between the filaments, and ſlightly curved like them; ſtigma uſually bifid. *Peric.* either wanting, as in the firſt order, where the calyx ſupplies its place; or capſular, ſometimes pulpy, and moſtly of two cells. *Seeds* if naked four, except in *Phryma;* if covered generally very numerous. The orders of this claſs are two: 1. *Gymnoſpermia*, in which the ſeeds are naked. Of this the plants are often aromatic, and never poiſonous. 2. *Angioſpermia*, ſeeds in a ſeed-veſſel, in which are many beautiful, though ſeveral poiſonous and fœtid plants. In this order, and in the former, though much more rarely, the flowers occaſionally become regular and then have five equal ſtamens, as in ſeveral ſpecies of *Antirrhinum*, and ſome *Bignoniæ* and *Chelones*. S.

DIE. See Dye.

Die, *Dea Vocontiorum*, in *Geography*, a ſmall town of France, in the department of the Drôme, chief place of a diſtrict of the ſame name, ſituated in a fine valley on the river Drôme; 27 miles S. E. of Valence, 45 N. W. of Gap, 36 S. W. of Grenoble, and 450 S. by E. of Paris. Lat. 44° 44′. Its canton has a territorial extent of 430 kilometres, 15 communes, and 7975 inhabitants, of whom the town itſelf contains 3968.

As chief place of a diſtrict, Die has a ſub-prefect, a court of juſtice, and a regiſter-office. Mount Orel, in its neighbourhood, has a ſpring of mineral water, which is conſidered as a ſpecific remedy againſt intermittent fevers.

The ſoil of the diſtrict of Die is mountainous and not very fertile: it produces, however, ſome corn, and has good orchards. The paſtures are favourable for the rearing of cattle. There are a few manufactures of woollen and linen cloth. The whole diſtrict counts nine cantons, 117 communes, and 58,090 inhabitants, upon a territorial extent of 2430 kiliometres.

Die, *Saint*, in Latin *Sanctus Deodatus*, a ſmall town of France, in the department of the Voſges, chief place of a diſtrict of the ſame name, ſituated on the river Meuſe, which runs through the town: 30 miles W. of Scheleſtat, 36 S. E. of Luneville. Lat. 48° 20′. The extent of its canton is 225 kiliometres; it has 22 communes, and 14,925 inhabitants, 5346 of whom inhabit the town. St. Dié has a ſub-prefect, a court of juſtice, and a regiſter office.

The plains in this diſtrict produce rye, oats, millet, and potatoes; the mountains are covered with foreſts of pine. The paſtures are good, and there is fine flax grown, of which the inhabitants make excellent linen cloth, tape, and thread; which articles, together with cattle, iron, hardware, jewellery, timber, and firewood, conſtitute their principal trade. There are copper mines at Luſſe, Fraize, and Lubirce, lead and ſilver mines at La Croix, and an iron mine at the foot of a mountain called the Donon. At Chipal there are alſo ſeveral kinds of mines, and a fine quarry of variegated marble. The diſtrict of St Dié has a territorial extent of 1515 kiliometres, nine cantons, 108 communes, and 75,298 inhabitants. —Alſo a ſmall town of France, in the department of the Puy-de-Dôme, chief place of a canton, in the diſtrict of Clermont, with a population of 1200 individuals. The canton has 10 communes and 12,727 inhabitants, upon a territorial extent of 177½ kiliometres.—Alſo, a ſmall town of France, on the river Loire, in the department of Loire and Cher, 12 miles E. of Blois.

DIEBACH, a town of the duchy of Luxemburg; four miles W. S. W. of Luxemburg.

DJEBAIL, the ancient *Byblos*, a town of Syria, the moſt

moſt conſiderable in the country of Keſraouan, which extends from Nahr-el-Kelb, paſſing by Lebanon, as far as Tripoli. It has not, however, above 6000 inhabitants. The ancient port reſembles that of Latakia, but is in a worſe ſituation; ſcarcely any traces of it remaining. The river Ibrahim, the ancient Adonis, two leagues to the ſouthward, has the only bridge to be ſeen, that of Tripoli excepted, from thence to Antioch. It has a ſingle arch, 50 feet wide, and upwards of 30 high; of an architecture, which appears to be the work of the Arabs.

DJEBAL, or HIGH-LANDS, one of the general diviſions of Yemen, in Arabia; the other being *Tehama*, or the Low-lands. The latter contains ſix of thoſe governments into which the kingdom of Sana is ſubdivided, and the former 24.

DIE'CKIRCH, a ſmall town of France, in the department of the Foreſts, (des Forêts) chief place of a diſtrict of the ſame name, on the river Sarre, with a population of 2513 individuals. Its canton has a territorial extent of 207½ kiliometres, 10 communes, and 8909 inhabitants.

As chief place of a diſtrict, Diéckirch has a ſub prefect, a court of juſtice, and a regiſter office. It contains many tan-yards, and ſome manufactures of woollen cloth. The vine grows on the hills in the neighbourhood of Vianden. There is a mine of very fine copper, the working of which is ſtopped for want of hands.

The whole diſtrict contains five cantons, 70 communes, and 38,128 inhabitants, upon a territorial extent of 1287½ kiliometres.

DIEDRAVA, a village of Ruſſia, on the road from St. Peterſburg to Moſcow; 361 verſts from St. Peterſburg.

DIEGO D'ALVAREZ, an iſland in the Southern Atlantic ocean, whoſe bearing and diſtance from the iſlands of Triſtan d'Acunha, according to the general chart of Capt. Cook's Third Voyage, are 38° 53′ S. and 13° W.

DIEGO *Garcia*, or CHAGOS, an African iſland in the Indian ſea. Rochon, in his "Voyage to Madagaſcar," ſays, that it is 12 leagues in circumference; and that its form reſembles a horſe-ſhoe. Its greateſt breadth is not above ¼ of a league: the ground, however, is ſufficiently elevated to ſerve as a fence and ſhelter to a vaſt reſervoir or canal, which affords ſpacious room to the moſt numerous fleets. This canal is four leagues long, and its main breadth about one league. Its excellent harbour has two entrances to the ſouth. The roads are very fine. He aſcertains its ſituation to be in S. lat. 7° 14′, and E. long. from Paris 68°.

DIEGO *de Ramirez*, an iſland near the coaſt of Terra del Fuego, S.S.W. of cape Horn. S. lat. 56° 39′. W. long. 68° 1¼′.

DIEGO *Rias*, or *Rodriguez*, an iſland of Africa, in the Indian ocean; 100 leagues E from the iſland of Mauritius, or iſle of France. S. lat. 19° 30′. E. long. 57° 32′.

DIEGO *Sourez*, an iſland in the Indian ſea, near the eaſt coaſt of the iſland of Madagaſcar.

DIEGO, *Cape*, *St.* the low point that forms the north entrance of the ſtrait of La Maire, on the eaſt coaſt of Terra del Fuego. S. lat. 54° 33′. W. long. 65° 14′.

DIELCYSTINDA, among the *Ancients*, a kind of exerciſe performed by boys, who, being divided into two parties, or ſides, each endeavoured to draw the other over to their ſide, and the party which prevailed gained the victory.

DIELE, in *Geography*, a river of European Turkey, which runs into the Pioth, near Czezora.

DIELETTE, a ſmall town of France, in the department of La Manche, with an inconſiderable harbour in the Engliſh channel, which was finiſhed in 1731; 5 miles S.W. of Cherbourg.

DIEM CLAUSIT EXTREMUM, in *Law*, a writ iſſued out of chancery to the eſcheator of the county, upon the death of any of the king's tenants *in capite*, to enquire, by a jury, of what lands he died ſeiſed, and of what value, and who was the next heir to him.

DIEMEN, ANTHONY VAN, in *Biography*, a governor of the Dutch Eaſt-India ſettlements, was born at Kuilenburg. He went, in early life, in a low military capacity to India, where he was chiefly employed in writing petitions for the ſoldiers. He was afterwards promoted to a poſt under government, which required ſome ſkill in accounts: hence he became a merchant, and afterwards accountant-general of the Dutch ſettlements in India. In 1625, he was appointed a member of the ſupreme council, and in 1631 he returned to Holland as commander of the India fleet. He remained but a few months in Europe, and when he went back to India many important offices devolved on him. In 1642, he ſent out two ſhips to explore the unknown countries to the ſouth, part of which, forming the ſouthern extremity of New Holland, was, in honour of him, diſtinguiſhed by the appellation of "Van Diemen's land." He died in April 1645, having held, with much reputation, the ſupreme power in India upwards of nine years. Gen. Biog.

DIEMEN, in *Geography*, a town of Holland; 4 miles S.E. of Amſterdam.

DIEMEN, *Straits of*, lie between the coaſt of Aſia, and the iſlands of Japan.

DIEMEN'S, or *Van Diemen's Land*, an iſland in the form of an oblong ſquare, about 160 Britiſh miles long, by half that breadth, ſeparated, by a ſtrait, or rather channel, more than 30 leagues wide, called, in recent maps, Baſs's ſtrait, and containing a chain of ſmall iſlands, running N. and S., from New Holland, ſo called by Taſman, in honour of the Dutch governor-general in the Eaſt Indies, who diſcovered it in November 1642. From that time, ſays capt. Cook, it had eſcaped all farther notice by European navigators, till captain Furneaux touched at it in March 1773; but he did not know at that time that capt. Marion, after having remained here for ſome time, ſailed from thence on the 10th of March 1772. It was again viſited by captain Cook in January 1777. The land is, for the moſt part, of a good height, diverſified with hills and vallies, and every where of a greeniſh hue. It is well wooded, and, if one may judge from appearance, ſays captain Cook, and from what we met with in Adventure bay, is not ill ſupplied with water. The beſt is a rivulet, which is one of ſeveral that fall into a pond, that lies behind the beach at the head of the bay. Fire-wood is to be obtained, with great eaſe, in ſeveral places. The only wind to which this bay is expoſed is the north-eaſt, which, blowing from Maria's iſlands, can bring no very great ſea along with it; and, therefore, this may be accounted a very ſafe road. The bottom is clean, good-holding ground; and the depth of water from twelve to five and four fathoms. The author has annexed a chart, which gives a better idea of this part of the coaſt than any deſcription. The following table will exhibit both the longitude and latitude at one view:

	Lat. S.	Long. E.
Adventure bay	43° 21′ 20″	147° 29′ 0″
Taſman's head	43 33 0	147 28 0
South cape	43 42 0	146 56 0
South-weſt cape	43 37 0	146 7 0
Swilly iſle	43 55 0	147 6 0

Adventure bay — Variation of the compaſs 5° 15′ E.; Dip. of the ſouth end of the needle 70 15½

The high water was, on the 29th of January, two days before the laſt quarter of the moon, at nine in the morning: the perpendicular riſe was then 18 inches; and there was no appearance of its ever having exceeded 2½ feet. The beautiful ſandy beach, at the bottom of Adventure bay, is about two miles long, and excellently adapted for hauling a ſeine,

a ſeine, which was repeatedly done with ſucceſs. The parts of the country adjoining the bay are quite hilly; and both theſe and the plain behind the beach, in which is a brackiſh lake, are an entire foreſt of very tall trees, rendered almoſt impaſſable by ſhrubs, brakes of ferns, and fallen trees; except on the ſides of hills, where the trees are thinly ſcattered, and intermixed with coarſe graſs. The ſoil on the low land, to the northward of the bay, is either ſandy, conſiſting of a white ſand-ſtone, which forms the Fluted cape, and bounds the ſhore, or conſiſts of a mould that is yellowiſh, or of a reddiſh hue. The ſame is found on the lower parts of the hills, and farther up, it is of a greyiſh caſt, and very poor. In the vallies there are ſome ſmall ſtreams; but the country appears to be naturally very dry. The heat alſo is great, as the thermometer ſtood at 64, 70, and once at 74 degrees; and birds were obſerved to putrefy in an hour or two after they were killed. The country has no minerals, nor, indeed, ſtones; and among its vegetable productions none were found that yielded the ſmalleſt ſubſiſtence to man. The foreſt trees are all of one ſort, growing to a great height, and generally ſtraight; and they ſeem to have ſome affinity to the *myrtus* of botaniſts. There are other ſmaller trees, and a variety of plants, which it is needleſs to enumerate. The only quadruped obſerved was a ſort of opoſſum, about twice the ſize of a large rat. However, the kanguroo is alſo an inhabitant of this part of the country, as the natives uſed pieces of its ſkin in their dreſs. Here are ſeveral ſorts of birds, which, being much haraſſed by the natives, who derive much of their ſubſiſtence from them, are very ſhy. In the woods the principal ſorts are large brown hawks or eagles, crows, yellowiſh parroquets, and large pigeons. On the ſhores were gulls and plovers. A few wild ducks were ſeen about the pond or lake behind the beach, and ſome ſhags were alſo obſerved. Some large blackiſh ſnakes were ſeen in the woods, and a lizard, 19 inches long and ſix round, elegantly clouded with black and yellow. The ſea was well ſtocked with various ſpecies of fiſh; but the elephant fiſh, or pejagallo, ſeemed to be the moſt numerous. Upon the rocks the muſcles and other ſhell-fiſh were plentiful; ſea-ſtars were numerous; ſponge, Meduſa's heads, and ſea-fuci were not uncommon. Of inſects there is a conſiderable variety. The inhabitants had little of that fierce or wild appearance, common to people in their ſituation; but ſeemed mild and cheerful, without reſerve, or jealouſy of ſtrangers. They appear to have little genius, or perſonal activity, either of mind or body; their greateſt ſkill is manifeſted in their manner of cutting their arms and bodies in lines of different lengths and directions, which are raiſed conſiderably above the ſurface of the ſkin, ſo that it is difficult to gueſs how they execute this embroidery of their perſons. Their colour is a dull black, and not quite ſo deep as that of the African negroes. Their hair is perfectly woolly, and it is clotted or divided into ſmall parcels, like that of the Hottentots, with ſome ſort of greaſe, mixed with a red paint or ochre, which they ſmear in great abundance over their heads. Their noſes, though not flat, are broad and full. The lower part of the face projects conſiderably; their eyes are of a middling ſize, with the white leſs clear than in ours; and though not remarkably quick or piercing, they gave a frank cheerful caſt to the whole countenance. Their teeth are broad, not equal nor well ſet; their mouths are rather wide; their beards are long, and clotted, like their hair, with paint. In other reſpects they are well proportioned; though the belly is rather projecting. Their habitations are wretched huts, formed of ſticks, apparently ſerving for a temporary purpoſe; but many of their largeſt trees were converted into more comfortable dwellings. The trunks of theſe were hollowed out by fire, to the height of ſix or ſeven feet, and in theſe hollows they took up their abode. The inhabitants of this part of the country are ſprung, without doubt, from the ſame ſtock with thoſe of the northern parts of New Holland; and the difference may be accounted for by diſtance of place, entire ſeparation, diverſity of climate, and other concurring circumſtances. But there is not the leaſt reſemblance in their language, a circumſtance which cannot be eaſily accounted for.

The natives approached our navigators, who had landed, without betraying any ſymptoms of fear, or rather, with the greateſt confidence imaginable. Labillardiere (ubi infra) aſcribes the gentleneſs with which they behaved to Capt. Cook and his companions to the dread of European fire-arms, excited by Capt. Marion's being under the neceſſity of uſing theſe arms againſt them. They were quite naked, and wore no ornaments, if we except the punctures and ridges already mentioned. They received every preſent that was made to them without the leaſt appearance of ſatisfaction, and they indicated a degree of ſtupidity. They ſeemed to ſet no value on iron or on iron tools; and they were even ignorant of the uſe of fiſh hooks. Some of them wore, looſe, round their necks, three or four folds of ſmall cord made of the fur of ſome animal; and others of them had a narrow ſlip of the kanguroo ſkin tied round their ancles. The females wore a kanguroo ſkin, juſt as it came from the animal, over the ſhoulders, and round the waiſt; but its only uſe ſeemed to be to ſupport their children, when carried on their backs; but it did not cover thoſe parts which the inhabitants of moſt nations conceal. The bodies of the women were marked with ſcars like thoſe of the men; but though their hair was of the ſame colour and texture, ſome of them had their heads completely ſhorn or ſhaved: others had this operation performed only on one ſide, while the reſt had the upper part of the head ſhorn cloſe, leaving a circle of hair all round, ſomewhat like the tonſures of the Romiſh eccleſiaſtics. The women rejected offers of addreſſes and preſents with diſdain: either from a ſenſe of delicacy and virtue, or from a fear of diſpleaſing their men. That this gallantry was not very agreeable to the latter was certain; becauſe an elderly man, as ſoon as he obſerved it, ordered all the women and children to retire, which they obeyed, though on the part of ſome not without reluctance. (Cook's Third Voyage, vol. i.) Of this iſland we have had ſome additional information by Mr. Collins, Capt. Flinders, as well as Labillardiere. The ſouth-weſt cape of Van Diemen's land, according to Mr. Collins, (Account of the Engliſh Colony in New South Wales, vol. ii. 1804,) is a narrow piece of land, projecting from the higher land at no great diſtance, with two flattiſh hummocks, reſembling the Ram Head, near Plymouth. The ſouth-weſt and ſouth capes lie nearly eaſt and weſt of each other, and are diſtant about 15 leagues. The intermediate coaſt forms the ſouthern boundary of Van Diemen's land. The extremity preſents a rugged and determined front to the icy regions of the ſouth pole, and like that of Terra del Fuego, ſeems once to have extended farther ſouth than it does at preſent. Its extraordinary elevation and irregular form entitle it to rank among the foremoſt of the grand and wildly magnificent ſcenes of nature. Lofty ridges of mountains, bounded by tremendous cliffs, project from two to four miles into the ſea, at nearly equal diſtances from each other, with a breadth varying from two miles to two and a half. The heights or bays lying between them are backed by ſandy beaches. Theſe vaſt buttreſſes appear to be the ſouthern extremities of the mountains of Van Diemen's land, which have, very probably, projected into the ſea far beyond their preſent abrupt termination, and have been united with the now detached

tached land, De Witt's iſles, ſo named, probably, by Taſman, which are twelve in number, and of various ſizes. The two largeſt are from three to four miles in circuit, with ſteep ſides, but with height inferior to that of the main: the largeſt is the loweſt. Their aſpect, like that of the main, beſpeaks extreme ſterility. After paſſing ſeveral places of ſmaller note, they entered Herdſman's cove; above which they went up the Derwent river in a boat. As they advanced, Mr. Baſs and his companion found the ſtream was 230 yards broad, and three fathoms deep. Here they met with a man, with hair which they did not think to be woolly, armed with two ſpears, very ill made, of ſolid wood. His aſpect was frank and open, and led them to form a favourable opinion of the diſpoſition of the inhabitants of the country in general. From various appearances they concluded, that the natives drew the principal part of their food from the woods; the bones of ſmall animals, ſuch as opoſſums, ſquirrels, kanguroos, rats, and bandicoats, were numerous round their deſerted fire-places, and the two ſpears juſt mentioned were ſimilar to thoſe uſed for hunting in other parts. No canoes were ever ſeen, nor any trees ſo barked as to anſwer the purpoſe of their conſtruction. Upon comparing Van Diemen's land with New South Wales, Mr. Baſs gives the preference, with regard to fertility of ſoil, to the former. Both countries reſemble one another in being amply furniſhed with water for the purpoſes of life; but in being deficient with reſpect to thoſe larger ſtreams, which ſerve to facilitate the operations of man, and convey commerce to the door of almoſt every inland farmer.

Captain Flinders, in his "Obſervations on the Coaſt of Van Diemen's Land, &c. 1801," ſays, that the capes are moſtly baſaltic, and he includes the "Fluted Cape;" the columns being ſometimes ſingle, ſometimes grouped like ſtacks of chimnies. Upon the iſland of "Cape Barren" are found kanguroos, and the new animal, called *womat* by the natives near Port Jackſon, reſembling a little bear. "Furneaux's iſles" are moſtly of a coarſe quartz, and likewiſe "Wilſon's Promontory," in New South Wales; while the general rocks in the laſt are ſoftiſh grit amid iron-ſtone. In general, Van Diemen's land preſents a moſt dreary and inhoſpitable ſhore, mottled with rocks of white quartz and black baſalt. Port Dalrymple is the only harbour upon the north coaſt, which ſeems the moſt fertile.

Labillardiere, in his "Voyage in Search of La Perouſe in 1791—1794," (vol. i.) furniſhes ſome intereſting details with regard to this iſland. He obſerves that, in the month of May, the ſummits of the higheſt mountains were whitened with ſnow; and that theſe mountains form part of a chain, which extends from ſouth-eaſt to north-weſt; whilſt another chain of great extent runs from north-eaſt to ſouth-weſt. In the iſland there are many rivulets and lakes. On the ſide of the mountains was obſerved an horizontal bed of coal, not exceeding in its greateſt thickneſs $3\frac{1}{2}$ feet, but extending for a diſtance of more than 200 fathoms; it reſts on free-ſtone, and is covered with a deep brown ſchiſtus. In theſe rocks were alſo found beautiful pieces of hematite, of a red copper colour, and of tripoli. The foreſts are thick, and not eaſily penetrated; and they conſiſt of many very tall trees, and others of a moderate height, which thrive well notwithſtanding the ſhade of the "eucalyptus globoſus," which is of an enormous ſize. Near the rocky bay, where the French navigators ſtopped, is a lake abounding with pelicans and black ſwans; and on the ſhores are many ſpecies of plants, ſeveral of them being new, which Labillardiere has particularly deſcribed, and of ſome of which he has given drawings. Among the animals are ſeen the kanguroo, which lives in burrows like the rabbit; the ſea-calf of the ſpecies called "phoca monachus;" a new ſpecies of parroquet, repreſented and deſcribed by our author under the name of the parroquet of Cape Diemen: another of "merops," deſcribed by White. Labillardiere's account of the inhabitants is very ſimilar to that of Capt. Cook. They did not flee at the approach of the French, and appeared to be mild and affable. The men and women were equally naked, or covered with a kanguroo ſkin. Their hair is woolly, and they let their beard grow; the upper jaw of children projects conſiderably over the lower, but falls back with increaſe of age, ſo that in adults it is in the ſame line: their ſkin is not very dark; but to increaſe its blackneſs, they cover themſelves with charcoal duſt, principally the upper parts of the body. They eat muſcles, oyſters, the large lobſter, and crabs which they broil: the women are chiefly employed in procuring food and preparing it. They do not appear to have any chiefs: each family ſeems to live in complete independence; but the children are very ſubordinate to their parents; and the women are ſo to their huſbands. They all appear unacquainted with the bow. Thoſe of Adventure Bay have their body tattooed, and their hair powdered with oker. Their domeſtic utenſils afford but an unfavourable ſpecimen of their ſkill and induſtry. There are baſkets clumſily conſtructed of the reed called *juncus acutus*, and drinking veſſels made of a large piece of *fucus palmatus*, cut into a circular form, and moulded into the ſhape of a purſe. They underſtand the art of procuring fire by ſtriking two pieces of flint together, in which reſpect they differ from the other inhabitants of the South Sea iſlands, and even ſome of thoſe of the more eaſterly part of New Holland; whence our author inclines to believe that they are deſcended from a different origin. Their thinly ſcattered huts indicated a very ſcanty population; and the heaps of ſhells found near the ſea-ſhore ſhewed that theſe ſavages derive their principal means of ſubſiſtence from the ſhell-fiſh which they find there. One of theſe navigators found ſome human bones among the aſhes of a fire made by the natives. Several bones of the pelvis he diſcovered by their form to have been part of the ſkeleton of a young woman: ſome of them were ſtill covered with pieces of broiled fleſh. Our author, however, is ſcrupulous of ranking the natives of this country with the cannibals: he rather ſuppoſes that they have the cuſtom of burning the bodies of their dead. As theſe were the only human bones diſcovered in this country, and theſe partly burnt, it appears that they do not expoſe the bodies of their dead to the open air. If it be not their cuſtom to burn their dead, they may poſſibly bury them in the earth, or throw them into the ſea.

As there is another Van Diemen's land, Mr. Pinkerton very properly ſuggeſts, that the above deſcribed land, which is one of the iſles of New Zealand, ſhould be called *Taſmania*, in honour of the diſcoverer: and thus the confuſion ariſing from a duplicate of names would be prevented.

Diemen's *Land*, the northern part of New Holland, diſcovered by a Dutch navigator, named Zeachen, who beſtowed upon it this appellation in honour of Anthony Van Diemen, governor-general in the Eaſt Indies, who returned to Europe with incredible treaſures in 1631. We may conclude that this governor encouraged ſuch diſcoveries, as his name was impoſed upon various regions in this part of the world. See New Holland.

DIEMERBROECK, Isbrand, De, in *Biography*, was born at Montfort, in the neighbourhood of Utrecht, in the year 1609. After taking his degree of doctor in medicine at Angers, he went to Nimeguen in 1636, and continued there, through that and the following years, freely attending the inhabitants who were afflicted with the plague, which raged with

with great violence, during that time. It was here that he collected obſervations on the nature and treatment of that diſeaſe, which he publiſhed in the year 1644, in 4to. at Amſterdam. As he followed the method, pretty generally adopted in all fevers, of keeping the patients, in warm, cloſe apartments, and gave them mithridate, and other heating medicines, called Alexipharmics, it may be ſuppoſed his ſucceſs was not remarkably great. The book, however, obtained great credit, and has paſſed through many editions. In 1642 he went to Utrecht, and was made profeſſor extraordinary in medicine. His lectures in medicine, and in anatomy, procured him great credit, and were no leſs uſeful to the univerſity, drawing thither a great conflux of pupils. In 1651, he was made ordinary profeſſor, he was alſo twice appointed rector of the univerſity, and continued in high eſteem to the time of his death, which happened Nov. 17, 1674. In 1649 he publiſhed "Oratio de reducenda ad Medicinam Chirurgia," and in 1664, "Diſputationum practicarum, pars prima et ſecunda, de morbis Capitis et Thoracis," 12mo. in which, Haller ſays, there are ſome curious and uſeful obſervations. His "Anatome Corporis Humani," which has paſſed through numerous editions, was firſt publiſhed in 1672, 4to. It is a compilation, but is interſperſed with ſome original obſervations. The plates are principally from Veſalius, and neither very elegant, nor very correct. In 1685, his works were collected and publiſhed together, under the title of "Opera Omnia," by his ſon Timanis de Diemerbroeck, in folio. This was reprinted in two volumes, 4to. and publiſhed at Geneva in 1687. It contains, beſides the works above-named, "A Treatiſe on the Meaſles and Small-pox, a Century of Obſervations in Medicine and Surgery, and a Third Part of Diſputations containing Accounts of Diſeaſes of the lower Belly." Boerhaave Methodus Studii Med. Eloy. Dict. Hiſt.

DIEMERIS, in the *Ancient Muſic*, a word uſed ſometimes alone, and ſometimes joined with the word phorbeia. It expreſſed a ſort of bandage, uſed by the ancients, to tie up the lower lip in playing on the pipe. The other kind of phorbeia conſiſted only of one perpendicular piece, which went down the cheek, and one tranſverſe one, which covered the whole mouth, but had a hole cut into it to admit the mouth-piece of the pipe See PHORBÆA.

DIENNE, in *Geography*, a ſmall town of France, in the department of the Cantal; 15 miles N. of St. Flour.

DIENSES, in *Ancient Geography*, a people of Gallia Narbonnenſis, placed in the vicinity of the Rhone.

DIENSIS COLONIA, a Roman colony in Pieria, a country of Macedonia. Ptolemy calls it *Dion*.

DIENVILLE, in *Geography*, a ſmall town of France, in the department of the Aube; 9 miles N.W. of Bar-ſur-Aube.

DJEOUABYS, a hoſpitable tribe of Arabs, compoſed of about 2000 men, and poſſeſſing about 60 horſes, who lead a ſhepherd's life, and encamp every winter on the banks of the Natron lake in Egypt with their flocks. During this time they are employed in carrying natron and prickly reeds; they have alſo ſome traffic in dates, which they fetch in caravans from Sioua in the Ammonian Oaſis, which is a journey of 12 to 15 days. Theſe Arabs are "marabouths," or peaceful people, who wander here and there to find water and paſture for their cattle. They never make war; and only take up arms for ſelf-defence, and this they rarely do; they almoſt always trade for money. They retain more than any other tribe their ancient cuſtoms; they are merely ſhepherds, and refuſe to cultivate the ſoil. Their manners are mild and ſimple; though they are ſubject to the occaſional turbulence of paſſion, particularly that of love, cloſely allied to jealouſy in the eaſt, and ſometimes hurrying them into the moſt cruel exceſſes. The cloathing of the Djeouabys, conſiſts of an *ibbram* and a *bernous*, a kind of cloak, ſimilar to the ſurplice of thoſe who officiate in the Romiſh church, made of white wool. This ſtuff, which is uſed for the cloathing both of the men and the women, is manufactured in Barbary, and it is bought at Cairo, but chiefly at Alexandria. The wealth of the Djeouabys, and of the Arabs of the deſert in general, conſiſts in camels and ſheep, whilſt that of the Arabs who dwell in villages, conſiſts in large cattle. The Arabs always carry with them a great part of their wealth, in order to furniſh their habitable camps. They preſerve their chopped ſtraw and their grain in large pits underground. The neighbourhood of a well of freſh water, a few ſlips of land of a ſcanty product, or ſalt lakes that can be wrought with ſome profit, determine theſe encampments. They poſſeſs beſides, at four or five leagues from the margin of cultivated countries, ſtorehouſes kept ſecure, and further on in the deſert depoſits under the ſand, known by ſome outward marks to the proprietors only. The Djeouabys, in order to prevent being pillaged by the wandering tribes, are obliged to receive them into their camps, and furniſh them with proviſions, and barley for their horſes. The Arabs of the deſert are of a very different diſpoſition and character: they are a lawleſs predatory race, and are commonly conſidered merely as robbers and aſſaſſins. The principal weapon of the Arabs is a pike, which they throw and wield with great dexterity. They manage their horſes with equal ſkill; but they never attack in line, but always like foragers, uttering at the ſame time loud cries and invectives; their ſtyle of fighting being merely that of light troops. They are in general but ill equipped; their fire-arms and powder are very bad; their balls are not well caſt; the powder is granulated in an inartificial manner, and is for the moſt part charcoal; which they carry in a wooden flaſk, and the balls ſeparately in a leathern bag, ſeldom charging their pieces with cartouches. As ſoon as the Arabs are apprehenſive of an attack, they ſeparate into ſeveral ſmall camps at a great diſtance from each other, and tie their camels to the tents, ſo as to be able to move off at a moment's notice. When one tribe is engaged with another, the women come within ſight of the combatants, playing on the tambourine, and ſinging ſtrains to excite their courage; the wounded are taken care of by their wives and miſtreſſes. The women hold valour in great eſtimation, and a chief covered with ſcars is the boaſt of the whole tribe; thus the ſupport of empires is the bond of union among theſe miſerable hordes of robbers. See BEDOUEENS.

DIEP BAY, a bay in the iſland of St. Chriſtopher, near Diep-bay town.

DIEP-BAY *Town*, or *Deep town*, a town on the north-weſtern coaſt of the iſland of St. Chriſtopher. N. lat. 17° 30'. W. lon. 62° 43'.

DIEPBOURG. or DIEBURG, a ſmall town of Germany, in the circle of the Lower Rhine, formerly in the electorate of Mayence, but ſince the peace of Luneville in the grand duchy of Heſſe Darmſtadt, one of the confederated ſtates of the Rhine.

DIEPENAU, a town of Germany, in the circle of Weſtphalia and county of Hoya; 21 miles S.S.W. of Hoya.

DIEPENBEKE, ABRAHAM VAN, in *Biography*, a painter and engraver, was born at Bois-le Duc, in 1607, and was at firſt a painter on glaſs, in which he excelled his cotemporaries; but, diſcouraged by a variety of accidents, he directed his attention to painting in oil. He reſided for ſome time in Italy, and became the ſcholar of Rubens, under whom he made great improvement. His invention was fertile,

tile, and his execution ſpirited; and if he had taken time to correct his firſt ideas, he would have produced works that might have given him rank among the firſt artiſts; but being much employed in making drawings for prints and books of prints, he hurried his compoſitions, without attending to the propriety of his choice. He is ſaid, however, to have imitated Rubens with ſucceſs; he coloured well, and gave great force to his paintings by his ſingular ſkill in the chiaro-ſcuro. He engraved ſeveral "devotional ſubjects" with great ſucceſs. Strutt and Pilkington.

DIEPHOLD, or rather DIEPHOLZ, in *Geography*, a ſmall town of Germany, in the circle of Weſtphalia, ſituated on the lake Dummer, (which ſee) 30 miles S. of Bremen, 36 N. W. of Minden, and 30 N. E. of Oſnabruck. Lat. 52° 45'. It is the chief place of a county of the ſame name, formerly in the electorate of Hanover, but now in the conſcription of the new kingdom of Weſtphalia.

DIEPPE, a conſiderable ſea-port town of France, in the department of the Lower Seine, chief place of a diſtrict of the ſame name, ſituated near the Engliſh channel, at the mouth of the river Béthune, 138 miles N. W. of Paris, and 42 miles N. of Rouen. E. long. 1° 12'. N. lat. 49° 55' 17". It is a handſome well-built town; the ſtreets are ſtraight and ſpacious, particularly the high ſtreet, (la grande rue) which runs all the length of the place, and is nearly a mile long. The church of St. James is a fine building. There are two ſuburbs, that which is called Le Paulet is chiefly inhabited by ſailors and fiſhermen. At the weſtern extremity of the town is an old, but irregularly and badly fortified caſtle; at the eaſt end is the harbour, in the ſhape of a ſemicircle, with two very fine moles of ſtrong brick-work.

Dieppe is one of the eleven quarters of the maritime diſtrict of Havre, and comprizes in its naval conſcription the leſſer ports of Berneval, Criel, and Le Tréport. As it is the neareſt ſea-port town to Paris, it ſupplies that capital with fiſh by means of light carts, called chaſſe marées, which travel night and day. Its principal fiſheries are, thoſe of the herring, whiting, and mackarel. The number of veſſels engaged in the herring fiſhery amounts, in times of peace, to 60 or 70, the average produce of which is from 84 to 120,000 barrels, worth from two to two millions and a half French livres. The barrel of ſalt herrings is generally ſold at 21 livres, freſh at 20, and red herrings at 16½ livres. During the ſhort interval of peace from 1801 to 1803 the annual produce was not more than 40,000 barrels. The whiting fiſhery laſts during the months of December, January, and February, and is chiefly for the Paris market. The average produce of the mackarel fiſhery is 280,000 livres. It employs from 40 to 50 veſſels.

In time of peace there are regular packet-boats between Dieppe and Brighton. The paſſage is only 66 Engliſh miles, and takes from 10 to 24 hours. The diſtance from London to Paris, by Brighton and Dieppe, is 87 Engliſh miles ſhorter than by Dover and Calais.

Next to the fiſheries, the moſt important trade at Dieppe is its thread lace manufacture; which, in 1788, occupied about 4000 married and unmarried females and children, chiefly fiſhermen's daughters and wives. Its annual produce was eſtimated at 400,000 livres. The merchants ſell the thread to the women, and pay them for the lace according to its value, which differs from ſeven-pence halfpenny a yard (aune) to fifteen and ſixteen ſhillings ſterling a yard. They uſe chiefly Flemiſh thread from St. Amand. Common lace conſumes more thread than the fine bone lace. A yard of fifteen-penny lace holds nine-pennyworth of thread, whilſt a yard of ſeven or eight ſhilling lace holds only about three-pennyworth of thread. The inferior workwomen earn but from three-pence to four-pence a day; the beſt from ſix-pence to eight-pence, and even a ſhilling a day.

The manufacture of ivory and bone toys, of excellent workmanſhip, and at uncommonly reaſonable prices, occupies ſeveral hundred hands at Dieppe. Its population amounts to 20,000 individuals. The territorial extent of the canton is 12 kiliometres and a half; it includes only two communes, and reckons, altogether, 20,500 inhabitants.

As chief place of a diſtrict Dieppe has a ſub-prefect, a court of juſtice, a tribunal of commerce, and a regiſter office. The ſoil of the diſtrict is very fertile, and produces all ſorts of corn, vegetables, fruits, hemp, and flax, but chiefly a plant called vetch, (la veſce) which is conſidered as an excellent fodder for cattle.

The diſtrict of Dieppe comprizes, upon a territorial extent of 1237½ kiliometres, eight cantons, 222 communes, and 106,082 inhabitants. Herbin. Statiſtique de la France.

DIEPPENHEIM, a town of Overyſſel; 20 miles E. of Deventer.

DIER. See DYER.

DIERNA, in *Ancient Geography*, a town of Dacia. Ptolemy.

DIERDORF, in *Geography*, a town of Germany, in the circle of Weſtphalia, and county of Wied Runkel, ſeated on the Wiedbach, with a caſtle, the reſidence of the counts. The inhabitants are induſtrious, and employed in agriculture and commerce; eight miles N. N. E. of Coblentz.

DIERNBACH, a town of Germany, in the archduchy of Auſtria; 11 miles S. of Steyr.

DIERNBERG, a town of Germany, in the duchy of Stiria; ſix miles N. of Nitterfeldt.

DIERNPACH, a town of Germany, in the archduchy of Auſtria, five miles E. of Mieſſau.

DIERNSTEIN, or TYRNSTEIN, a ſmall town of Auſtria, in that part which is called Lower Auſtria, or the country below the Ens, in the circle above the Manhartſberge (circulus ſupra montem Meinhardi.) It is ſituated near the Danube, and famous for being the place where king Richard was diſcovered and confined, in 1194, by Leopold; and where a diviſion of the French army, of but 5,000 men, commanded by general Gazan, fought their way through 20,000 Ruſſians in the year 1805.

DIERVILLA, in *Botany*. See LONICERA.

DIES. See DAY.

DIES, in *Common Law*. There are two kinds of days, *juridici*, & *non juridici*.

DIES *juridici*, or *faſti*, are all days wherein juſtice is adminiſtered in court.

DIES *non juridici*, or *nefaſti*, are all Sundays in the year: and in Eaſter term, the feaſt of the Aſcenſion of our Lord: in Trinity term, the Nativity of St. John the Baptiſt: in Michaelmas term, the feaſt of All Saints, and All Souls: and in Hilary term, the Purification of the Bleſſed Virgin.

The ſame diſtinction holds not only as to legal proceedings in court, &c. but alſo as to contracts.

DIES, in ſome *Ancient Authors*, is alſo uſed for daily proviſion. "Et reddebat dimidium diem mellis, *q. d.* as much honey as ſerved the king's family half a day."

DIES *datus*, is a day, or time of reſpite given to the tenant, or defendant, by the court.

DIES *Marchiæ*, was a day of congreſs, or meeting of the Engliſh and Scots, appointed annually to be held on the marches or borders, to adjuſt all differences between them, and preſerve the articles of peace.

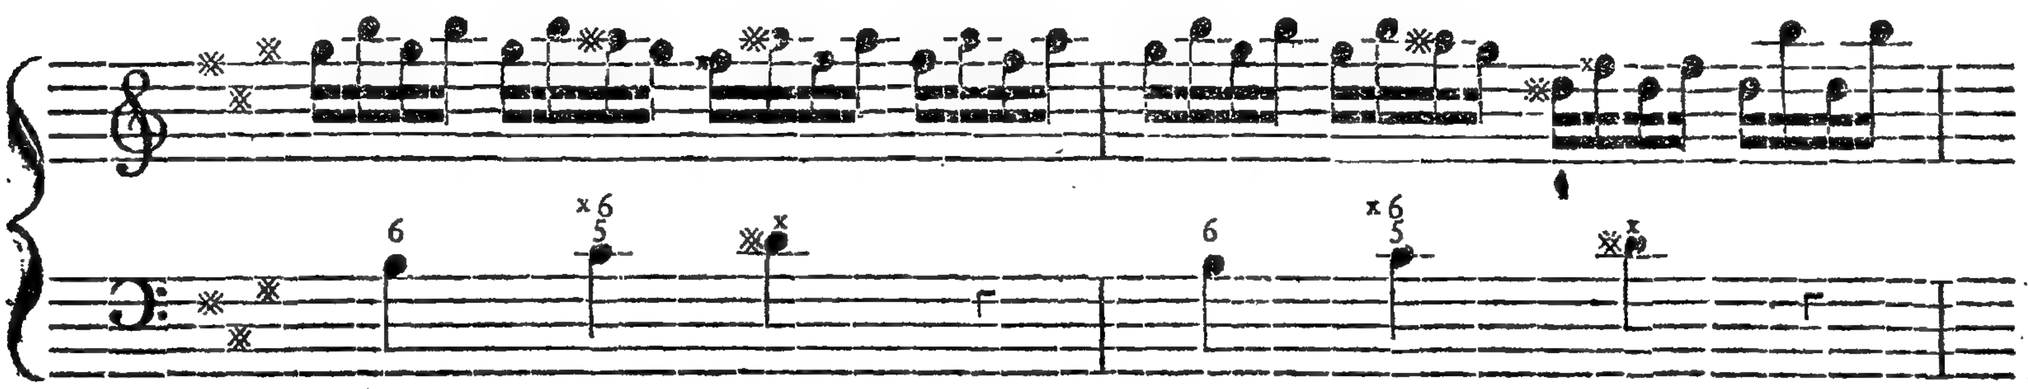
DIESBACH, in *Geography*, a ſmall town of Switzerland, in the canton of Berne, remarkable for its excellent

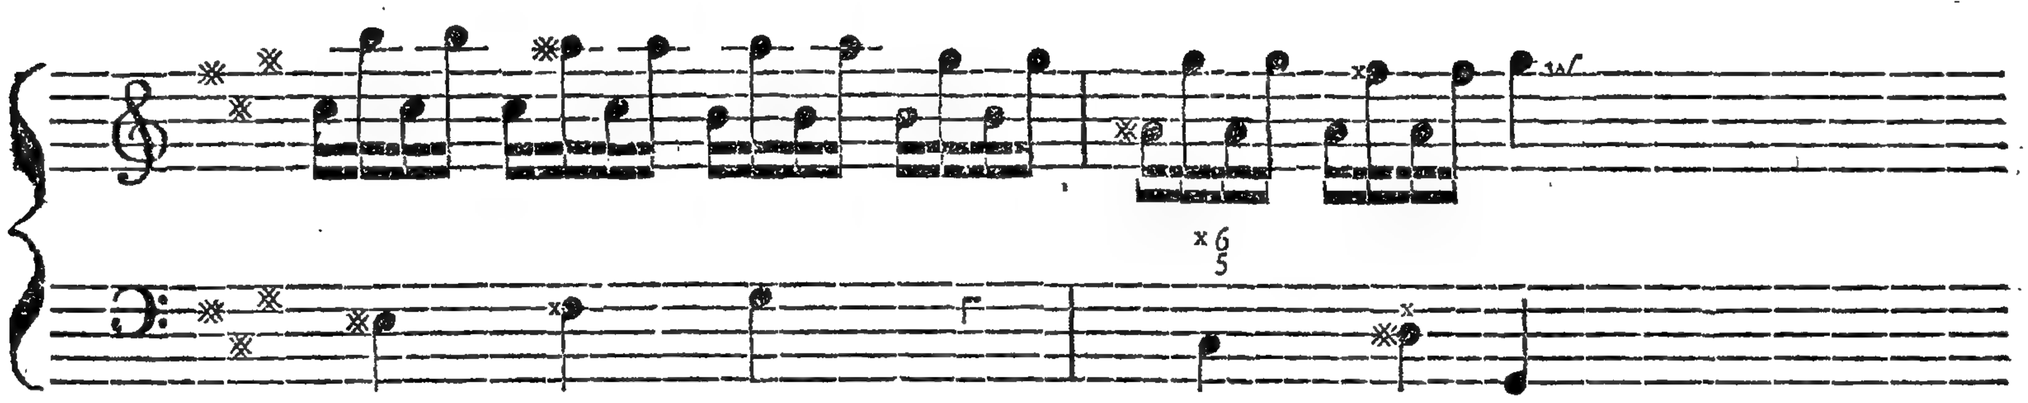
manufactures of coarſe and fine woollen cloth and linen cloth of a ſuperior quality.

DIESIS, in the *Ancient Muſic*, was the enharmonic ſharp, ×; in the modern Italian muſic it implies a common ♯ or minor ſemitone. See SHARP and ENHARMONIC. The order in which the ſharps are placed at the clef is by fifths, in the following manner: F C G D A, &c. The uſe of a ♭ and ♯ in the middle of a movement extends no further than a ſingle bar, unleſs the laſt note of a bar is ſharp, and is repeated or continued by the firſt note of the next bar; then the ſharp of the firſt bar need not be repeated, but is underſtood, unleſs contradicted by a ♮. Flats and ſharps at the clef are to regulate the ſemitones of tranſpoſed keys. In major keys, aſcending, the ſemitones are from the third to the fourth and from the ſeventh to the eighth, and in minor keys, deſcending, without accidental ſharps, or flats, they lie from the ſixth to the fifth and third to the ſecond.

The French and Italians have no other word to expreſs a ♯ or minor ſemitone, than *dieze* and *dieſis*.

The enharmonic ſharp, or quarter-tone, in the Greek muſic marked with a ſingle croſs ×, is uſed in modern muſic for a double ſharp; as in a key with many ſharps at the clef, if it is neceſſary to elevate one of the ſounds already ſharp a nominal half note, it is (or ſhould be) expreſſed by an enharmonic di-ſis, thus: as in Corelli's XIth ſolo.





The dieſis, or common ſharp, is inadmiſſible in canto fermo. P. Martini.

DIESIS *Enharmonic*, in *Muſic*, is an interval ſo named by Rameau. Overend, &c. whoſe ratio is $\frac{125}{128}$, and its common logarithm .9897000,4336. It is alſo the dieze major of Rameau; the harmonia of Henſling; the apotome major of Saloman de Caus, Boetius, &c.; the minor enharmonic quarter tone of ſome; the quarter note or quarter tone of Dr. Boyce and others: the tierce wolf of earl Stanhope, and the comma greater of ſome. It is equal to $21\,\Sigma + 2\,m$, $= 1.909170$ times the major comma. In Euler's logarithms, or decimals of an octave, it is $= .0342157$. It reſults from the addition of the following intervals, *viz.* a major comma and a minor comma; a ſchiſma and two minor commas; and a major reſidual and an hyperoche. This interval will alſo be found as the difference of the following intervals; *viz.* a major comma from a ſemitone minimum; a ſemitone minor from a ſemitone major; a ſemitone ſubminimis from a limma; a ſemitone medius from a ſemitone maximum; an hyperoche from a ſemitone minor; two ſemitones minor from a minor tone; a ſchiſma from two minor commas; a minor tone from two major ſemitones; three ſchiſmas from two diaſchiſmas; three major thirds from an octave; and three minor ſixths from two octaves; alſo two major thirds from the ſum of a minor fourth and minor third. The three laſt furniſhing us with practical methods of tuning an enharmonic dieſis upon an organ, &c.

DIESIS *Major* of Maxwell; this interval has a ratio of $\frac{2025}{2048}$, $= 10\,\Sigma + m$; and is the *minor* COMMA, which ſee.

DIESIS *Minor* of Maxwell; this interval has the ratio of $\frac{32768}{32805}$, $= \Sigma$, and is the SCHISMA, which ſee.

DIESIS *Major* of lord Brouncker; the ratio of this interval is $\frac{24}{25}$, $= 36\,\Sigma + f + 3\,m$, being the *Minor* SEMITONE, which ſee.

DIESIS *Chromatic*; this interval has a ratio of $\frac{16,384}{15,625}$, $= 26\,\Sigma + f + 2\,m$, its common logarithm is .0871761,5779. It reſults from the addition of the following intervals; *viz.* a ſchiſma, and ſemitone ſubminimis; and the major comma, and hyperoche; alſo, as the difference of the following, *viz.* an enharmonic dieſis from a medius ſemitone; a minor comma from a minor ſemitone; a major reſidual from a ſemitone minimum; two minor commas from a limma; two enharmonic dieſes from a ſemitone maximum; and three minor fourths from four major thirds, the laſt furniſhing a method of tuning a chromatic dieſis on an organ, &c.

DIESIS of Dr. Smith. This author, in his Harmonics, has conſidered various tempered ſyſtems, whoſe ſeveral octaves he makes to conſiſt of five equal tones, and two equal limmas; in each of which he calls the difference between the tone and limma the minor limma of that ſyſtem; and he alſo denominates the difference between the major and minor limma the dieſis of each ſyſtem; for example, (page 223) he calculates the dieſis, in his ſyſtem of equal harmony, to be in common logarithms $= .9879016.993$.

DIESIS *quadrantalis* of Euclid, is the $\frac{1}{10}$th part of the minor fourth, or $25\,\frac{2}{5}\,\Sigma + \frac{1}{2}f + 2\,\frac{1}{5}\,m$.

DIESIS *trientalis* of Euclid, is the $\frac{2}{15}$th part of the minor fourth, $33\,\frac{12}{15}\,\Sigma + \frac{2}{3}f + 2\frac{14}{15}\,m$.

DIESIS of Boethius, is half of the limma, or $23\,\Sigma + \frac{1}{2} + 2\,m$.

DIESIS of Mercator, is ſtated to be $\frac{2}{53}$d part of an octave, or $23\,\frac{5}{53}\,\Sigma + \frac{24}{53}f + m$.

DIESIS

DIESIS *quadrantal* of Ariſtoxenus, is the $\frac{1}{4}$th part of a major tone, or $26\,\Sigma + \frac{1}{2}f + 2\,\frac{1}{4}\,m$.

DIESIS *triental* of Ariſtoxenus, is the $\frac{1}{3}$d part of the major tone, or $34\,\frac{2}{3}\,\Sigma + \frac{2}{3}f + 3\,m$.

DIESIS of Martianus Capella, is an interval very nearly equal to $7\,\frac{1}{2}\,\Sigma + \frac{3}{5}\,m$; of which he ſtates, that 38 of them, and 19 ſemitones minor, make up a major twelfth; and alſo, that 34 of them, and 17 ſemitones minor, make up the minor eleventh.

DIESPITER, in *Antiquity*, a name given to Jupiter.

Some authors will have it the ſame with *Dios Pater*, Jupiter father; Jupiter being called in Greek Ζευς, or Δευς, whence the oblique caſe Διος, &c. Others hold Dieſpiter to ſignify *Dii pater*, father of the day. St. Auguſtin derives the name from *dies*, day, and *partus*, production, bringing forth; it being Jupiter that brings forth the day. Of which ſentiment were Servius and Macrobius; the former adding, that in the language of the Oſci they called him *Lucentius*, as Dieſpiter in Latin.

Struvius, Antiq. Rom. Synt. C. I. ſeems to intimate, that Dieſpiter ſignified Pluto; but, if that be his meaning, he is apparently miſtaken. For both in Cicero, and in the inſcription, he quotes from Gruter, xxi. 8. we have only *Dis pater*, and not Dieſpiter.

DIESSE, or TESSENBERG, in *Geography*, a beautiful high valley of Switzerland, in the canton of Berne, about eight miles long, and ſix broad, containing two pariſhes in the clerical juriſdiction of Nidau. The inhabitants ſpeak French, and are of the Proteſtant religion.

DIESSENHOFEN, an ancient town of Switzerland, in the canton of Thurgau, ſituated on the Rhine. Its ſtreets are regular and ſpacious, and it has ſeveral very fine buildings, but only one church, in which the Proteſtants and Roman Catholics alternately perform divine ſervice. Hartman, count of Kibourg, is ſuppoſed to have founded this place, or at leaſt walled it in, about the year 1178. From him it devolved to the counts of Habſburg, and was taken from the houſe of Auſtria by the Swiſs in 1460.

DIESSENSTEIN, a town and caſtle of Germany, in the circle of Bavaria; 12 miles N. of Paſſau.

DIEST, ADRIAN VAN, in *Biography*, a painter and engraver, was born at the Hague in 1655, but reſided chiefly in England, where he painted landſcapes with great ſucceſs; forming his taſte for this ſpecies of painting, from a contemplation of the ſcenes which he ſurveyed along the coaſts, in the weſtern parts of this kingdom. If this artiſt had met with encouragement adequate to his genius, he would probably have arrived at a ſuperior degree of excellence; but being obliged to paint pictures at low prices, he had not leiſure to beſtow upon them ſufficient ſtudy; and, therefore, his works are very unequal. Some of his pictures, finiſhed in his beſt manner, poſſeſs great clearneſs and tranſparence in the colouring, and a peculiar tenderneſs in the diſtances; in the ſkies they are truly fine, in the clouds they have an uncommon freedom, and through the whole they are diſtinguiſhed by an agreeable harmony. This maſter has etched in a ſlight, but maſterly ſtyle, ſeveral ſets of ſmall landſcapes. He died in 1704. Pilkington and Strutt.

DIEST, in *Geography*, a town of France, in the department of the Dyle, chief place of a canton in the diſtrict of Louvain, ſituated on the river Demer, three miles E. of Montaigu, and 14 N. of Tirlemont. N. lat. 50° 59′. It has ſome manufactures of woollen cloth and worſted ſtockings. Its population amounts to 5053 individuals. The canton contains 13 communes, and 13,883 inhabitants, upon a territorial extent of 215 kiliometres.

DIET, Δίαιτα, *diæta*, in *Medicine*, the regimen in reſpect to food and drink, adopted more particularly with a view to the prevention and cure of diſeaſes.

The importance of a proper regulation of the diet in preſerving the health, even of the moſt robuſt, cannot for a moment be queſtioned; but it would appear that both phyſicians, in their theoretical diſquiſitions on this ſubject, and mankind, in their practical application of the reſults, have fallen into frequent errors, but of a different nature. Phyſicians have often diſcuſſed the modifications of diet, both in health and diſeaſe, with too many minute and ſubtle diſtinctions as to the wholeſomeneſs of individual articles, and with too rigid an application of their general rules. And men, on the other hand, conſidering only the general notion of the ſalutary nature of this or that ſubſtance, have forgotten that the regulation of the quantity is not leſs important than caution as to the quality of their food. As to the quality of our diet, indeed, an over-anxious obſervation of rules and precepts is to be deprecated; it has frequently been the occaſion of injury to the healthy, as Dr. Heberden has juſtly remarked, and has not ſeldom augmented the indiſpoſition of the ſick. Cuſtom and experience have long ſince taught mankind what food and what regimen are uſeful and wholeſome to the generality of men; and among thoſe matters, which are generally wholeſome, no particular article is to be avoided; unleſs individual experience has pointed out ſome peculiar conſtitutional diſpoſition to be affected by particular ſubſtances. For, in other reſpects, thoſe who are not deficient in common judgment, will readily aſcertain what forms and modes are more congenial with their individual conſtitution.

If we look into the hiſtory of mankind, inhabiting the different parts of the globe, ſo far as we are acquainted with it, we ſhall find that different nations ſubſiſt on kinds of diet very different from each other, yet all enjoy a degree of health, which renders them competent to their duties in life in the countries which they inhabit. A great part of the eaſtern world is principally ſubſiſted by rice and vegetables; the inhabitants of many countries live upon fiſh; others on a mixed diet, partly animal, partly vegetable. Some have no fermented liquors; others uſe theſe only. Yet all, compared with each other in the ſame community, are healthy. The author of nature has ſo conſtructed us and our organs of digeſtion, that we can gradually accommodate ourſelves to every ſpecies of aliment; to live on rice, on vegetables, on animal food ſolely, or mixed with vegetables, without ſuffering injury. Nay, we can ſubſiſt on every variety of theſe ſubſtances, under every mode of preparation, preſerved in ſalt, hardened in ſmoke, pickled with vegetable acids, &c. as is exemplified in different countries, and in different ſeaſons of the year. In a word, no *kind* of food injures us; we are capable of being habituated to every ſpecies, and of converting into nutriment almoſt every production of nature. It is obvious, therefore, that in a ſtate of health, the conſideration of the quality of our victuals is of leſs importance than it has frequently been deemed. We are often aſked, ſays Dr. Fothergill, what our opinion is reſpecting certain articles of food, as to their being more or leſs wholeſome. "Perhaps the moſt pertinent anſwer in common would be, that which is reported of the late Dr. Mandeville, of famous memory, who being often the convivial gueſt, I think it was of one of the firſt earls of Macclesfield, was frequently interrogated on the ſubject of diet. Doctor, is this wholeſome? Does your lordſhip like it? Yes. Does it agree with your lordſhip? Yes. Why then it is wholeſome." See Medical Obſervations and Inquiries, vol. vi. p. 119.

But, even to the healthy, an attention to *quantity* is by no means unimportant. There are many people, indeed, who ſeem to be poſſeſſed of ſuch powers of digeſtion, as to be

under no reſtraints on that account, and who ſeldom feel themſelves incommoded, either with the quantity or with the moſt heterogeneous qualities of their food. They riſe from the moſt plentiful, mixed, and rich repaſts, without any kind of apparent uneaſineſs. But even the robuſt are not perfectly ſecure from the dangerous effects of a full meal. "Apoplexies," ſays the experienced phyſician juſt quoted, "proceed, perhaps, more frequently from this cauſe, than all the reſt put together." Of this remark, indeed, our newſpapers afford abundant corroboration; ſince nothing is more common than accounts of the ſudden death of individuals, "who appeared to be in perfect health, and had juſt eaten a hearty dinner," or "who had gone to bed in apparent good health, after having enjoyed a hearty ſupper," and ſo forth. It has been thought, ſays Dr. Fothergill, that more people ſuffered by hard drinking than immoderate eating. My obſervation leads me to take the oppoſite ſide. At preſent, indeed, the former practice is generally baniſhed to the vulgar, but whilſt it prevailed to the utmoſt, it ſeems to me that more were injured by exceſs of diet than of drinking. *Loc. Cit.*

"The firſt phyſicians by debauch were made,
Exceſs began, and ſloth ſuſtains the trade."

In fact, it is a doctrine, however trite and familiar, which cannot be too ſtrongly inculcated; as a neglect of this attention to the *quantity* of the food, proportioned to the neceſſity of each individual, is ſooner or later followed with the moſt ſerious conſequences. To the ſtrong and robuſt inflammatory diſeaſes happen, and all ſuch as proceed from plenitude, as the gout, apoplexy, palſy, lethargy, and a variety of chronic indiſpoſitions. To the more tender and delicate, it is the parent of a numerous progeny of diſtempers, affecting both body and mind; there is ſcarcely a malady that can be named, which either does not originate from this neglect of diet, or is not increaſed by it, till the diſeaſe at length bids defiance even to temperance itſelf, and all preſcription. The *how much*, indeed, muſt be determined by every individual; but thoſe who are happy enough to abſtain at the firſt ſenſation of ſatiety, have made great progreſs in the art of maintaining ſuch a command of appetite, as, under moſt chronic indiſpoſitions, is one of the greateſt aids of recovery; and, in health, is one of the ſureſt preſervatives againſt them.

To the delicate and valetudinary the conſideration of the quantity of the food is of ſtill more importance. They do not riſe from rich and varied repaſts with the ſame freedom from uneaſy ſenſations, as the robuſt; they are affected with uneaſineſs, ſome in one way, ſome in another, by the unnatural load. And we often hear them complaining of the ill effects of this or of that particular kind of diet, when, perhaps, their ſufferings ariſe from the quantity of all, rather than from the diſagreement of any.

What renders an attention to the quantity of food in invalids ſtill more neceſſary, is, that they are often ſubject to a falſe appetite; to a craving that does not ariſe from the demands of health, but from the morbid condition of the juices in the ſtomach, which prompts them to eat more, and more frequently than nature requires. Whence it happens that ſuch people are often diſpoſed to take in much more than can be digeſted, to devour their food rather than eat it; by which means their ſufferings are increaſed, the diſeaſe gains ground, defeats every purpoſe of the phyſician, and leads them into ſome permanent and incurable malady. And ſhould the patients have admitted an opinion, (and ſuch an opinion occurs but too often) that their recovery will be aided by taking in a greater ſhare of food, their misfortune is complete. Theſe are not ideal traits in the hiſtory of the ſick; they are known to be but too true by every phyſician of obſervation; and they cannot be mentioned too often, or with too much fervency, for the ſake of thoſe who are liable to become the victims of appetite or inattention. Early habits of ſelf-command are of the utmoſt benefit to all; and even thoſe who feel no immediate diſtreſs from the utmoſt repletion at preſent, would find it their intereſt to be moderate and diſcreet. Fothergill.

The cuſtom of countries, in reſpect to meals, are different. Breakfaſt, dinner, and ſupper, in this country, have been habitual. Suppers, at preſent, are diſcouraged among the affluent; and exceſſive ones, ſuch as have been in uſe among our anceſtors, very probably with good reaſon. Or, perhaps, we ſhould rather conſider the meal of dinner to have been diſcarded, and an early ſupper ſubſtituted; a change which, on the whole, is to be conſidered as detrimental, at leaſt to invalids and perſons of delicate habit. Two very moderate meals, at a ſuitable diſtance of time, would doubtleſs be digeſted with much more eaſe than one full meal, when the ſtomach has been debilitated by long faſting, and has ſuffered fatigue, together with the body at large, from the exertions of a long day. So that, as Dr. Fothergill has obſerved, "when people aſſure us that they eat no ſuppers, from obſervation I am led to ſuſpect, that it would be better for them if they did, than to oppreſs nature with a cumbrous load, that may be much more detrimental." This, indeed, ſeems to be pretty well underſtood, with reſpect to invalids and convaleſcents, who are generally ſupplied with ſmall light meals, at proper intervals, rather than have all their diet crowded into one late dinner.

The general breakfaſt of people, from the higheſt to the loweſt, is tea, coffee, or chocolate. There are, of courſe, many exceptions; ſome for one reaſon, ſome for others, making choice of other ſubſtitutes, as their experience or opinions guide them. To theſe articles bread of ſome kind, with more or leſs butter and ſugar, is commonly joined to make up the meal. From many inconteſtible proofs, that butter in conſiderable quantities is injurious to conſtitutions not ſtrong, it is ſparingly uſed in many families. It is found by many to be very difficult of digeſtion, eſpecially when toaſted before the fire, or fried, as well as in ſauces. Many people, apparently robuſt, and whoſe organs of digeſtion are ſtrong, often find themſelves much diſordered by large quantities of butter. Nothing more ſpeedily and effectually gives the ſick head-ache, and ſometimes within a very few hours. After breakfaſt, if much toaſt and butter has been uſed, it begins with a ſingular kind of glimmering in the ſight, objects ſwiftly changing their apparent poſition; giddineſs then comes on, head-ache, and ſickneſs. An emetic, and warm water, ſoon waſh off the offending matter, and remove theſe diſorders. Theſe are circumſtances which very often happen to people who are inattentive to the quantity of butter they eat at breakfaſt. A moderate quantity of freſh butter, with bread expoſed as little to the fire as poſſible, or not at all, appears to be wholeſome, and is capable of becoming with the other aliments, as ſoft and inoffenſive chyle, perhaps, as any part of our diet.

The ſame thing may perhaps be ſaid of coffee, as of tea; the heat, the ſtrength, and the quantity, make it unwholeſome or otherwiſe. There are nations who almoſt live upon coffee, as others do on tea; and among neither are any diſeaſes prevalent, that can juſtly be aſcribed to theſe ingredients in the common courſe of living. There are, however, individuals of peculiar conſtitution, in whom the Indian tea excites various unpleaſant ſymptoms, as head-ache, reſtleſſneſs, &c.; and ſeveral Britiſh plants have been recommended

mended as ſubſtitutes, and uſed with advantage. Such are ſage, balm, mint, and the like; the leaves of the different ſpecies of roſe-tree, and of the ſloe-tree, or black thorn, (*prunus ſpinoſa*, Linn.) are recommended by Dr. Withering, eſpecially the latter, the leaves of which, dried, he eſteems the beſt ſubſtitute for tea that has yet been tried. Dr. Willich recommends the flowers of the *roſa pimpinelliſolia*, of the woodroof, *aſperula odorata*; but adds that the firſt tender leaves of the whortle-berries, *vaccinium myrtillus*, cannot be diſtinguiſhed from real tea, when properly gathered, and dried in the ſhade. (Lectures on Diet and Regimen, p. 417.) It ſhould be recollected, however, that every vegetable infuſion of this ſort, is but warm water, rendered more palatable by the aroma of the herbs ſo infuſed; and that there is little or no nutriment conveyed by them to the body, except what is contained in the ſmall portion of milk and ſugar added to them. Theſe liquors, then, ſhould be conſidered as the mere beverage, by which the ſolid portion of the breakfaſt, the bread, &c. is to be diluted, and its digeſtion aſſiſted: and it would be adviſable for the delicate and valetudinary to curtail the liquid, and augment the ſolid part of a meal, which is to ſupport them during the exertions of the day, rather than to fill the ſtomach with a diluent and narcotic liquid, at once failing to nouriſh the body, and depreſſing the action of the ſtomach, where little is taken beſides.

Chocolate, which is the fruit of a tree growing in the Weſt Indies, ground into a paſte, with other ingredients, is in itſelf a nutritious ſubſtance, and to thoſe who like it, and with whom it agrees, it may be conſidered as a wholeſome breakfaſt. The ſame may be ſaid of milk, eſpecially of that from which ſome of the oleaginous part, the cream, has been taken away, and which has been afterwards boiled. Both theſe matters are ſo oleaginous that little or no butter ſhould be taken with them.

But the effects of improper conduct in reſpect to thoſe things which now conſtitute our breakfaſts, are of little conſequence, compared with thoſe which ariſe from the well-covered table at dinner. The indulgences of breakfaſt ſupply but very few materials for deſtruction; but the repeated exceſſes at dinner are ſerious affairs. And although, as we have before ſtated, the quantity of food is the point to be principally regarded; yet the quality is by no means a matter of indifference to the valetudinary.

The principal admonition, which the late Dr. Heberden deemed it neceſſary to impreſs on the minds of delicate perſons and invalids, was to avoid all thoſe artificial ſtimulants of the appetite, which excite the deſire for food beyond the ſimple call of nature, and, therefore, beyond the natural powers of the ſtomach to digeſt. Such are all made diſhes, and condiments of the more poignant qualities; nor is variety of diſhes leſs pernicious, upon the ſame principle. (See Heberden Comment. de Morbor. Hiſt. et Curat. cap. i.) It is probable that, in their nature, aromatic vegetable condiments, or ſpices, are leſs pernicious to the organs of digeſtion, than the various modifications of alcohol, or ſpirits; but the miſchief which they occaſion indirectly, by leading to exceſs, is unbounded. This exceſs is ſtill more pernicious, now that the hour of dinner is poſtponed to the evening; for the ſtomach is enfeebled by the long abſence of ſtimulus, and by ſympathizing in the fatigue of the body, ſo that its power of digeſting a copious and heterogeneous maſs is greatly diminiſhed; it is loaded, and diſtended, and oppreſſed; and the body, in its turn, ſuffers with the ſtomach. Hence, we ſee the fluſh of the countenance ſucceeding to a late and copious dinner; the indiſpoſition to any active exertion, mental or corporeal; the general oppreſſion of the animal powers; the heavineſs to ſleep; and the general ſenſation of heat; the hurried pulſe; dry or clammy tongue; and other ſymptoms of ſlight feveriſhneſs. It is moſt obvious, that the daily, or even frequent repetition of ſuch a diſorder, (for it is, in fact, a morbid condition which is thus produced,) cannot be ſuffered, without injury to the conſtitution. That this is no imaginary deſcription, the feelings of every valetudinary, who thus ſubmits to the controul of a pampered appetite, will teſtify.

Some of the common articles of diet require a little attention. Bread, the ſtaff of life, is not the moſt eaſy of digeſtion; if taken in conſiderable quantity, very ſtrong organs are requiſite to convert it into nutriment, and more eſpecially when it is new, or recently baked; for then it is of a glutinous and heavy nature, and extremely difficult of ſolution. Caſes have been recorded, indeed, in which an immoderate quantity of freſh-baked bread proved the cauſe of death. (See London Med. Journal for 1781, vol. i. p. 333.) In weak ſtomachs a large proportion of bread is indigeſtible; it turns ſour, produces the heart-burn, flatulencies, and interrupts the perfect concoction of every thing elſe. On this principle, the neceſſity of paying much attention to this capital article of diet, ought to be inculcated on valetudinaries in general; never to abſtain from it wholly, but to uſe it with moderation; to conſider it as one of thoſe things which, ſparingly uſed, is extremely neceſſary and beneficial; if otherwiſe, the fruitful ſource of many complaints, which are little ſuſpected from this cauſe.

In this country, animal food, of one kind or another, conſtitutes the chief part of our nouriſhment. That there are ſome kinds of more eaſy, ſome of harder digeſtion, is well known to every one; ſo that it is unneceſſary here to particularize them. The young of animals is generally conſidered as more eaſily ſoluble than the old; but in ſtomachs diſpoſed to acidity, this does not appear to be the caſe. Animal food is rendered more digeſtible, by approaching to a ſtate of beginning putrefaction; hence, the fleſh of animals recently killed is leſs eaſy of digeſtion than that which has been kept for ſome time; and hence, alſo, the fleſh of an animal which has been hunted, or has uſed any violent exertions before death, is more tender and wholeſome, than one which has been in confinement; for, after ſuch exertions, the muſcular or fleſhy parts are diſpoſed to go ſpeedily into a ſtate of putrefaction. On the contrary, the regular continued action of the muſcles, during life, hardens them, and renders them more difficult of ſolution in the ſtomach. Thus, the legs of poultry, which are in conſtant exertion, are harder than the fleſh of the wings, or of the breaſt, becauſe theſe muſcles are ſeldom exerted in flying. There can be no doubt, however, that ſcarcely any modification of animal diet would generally diſagree, *i. e.* would be digeſted with difficulty and uneaſineſs, if we were fully as anxious, in reſpect to exceſs of quantity, as to the unſuitableneſs in kind. If a perſon eats as much of ham, ſalted beef, or bacon, as he ought to do of fiſh or chicken, he may ſuffer by it.

Fiſh holds a ſort of intermediate rank between animal and vegetable matters, as to the quantity of nutriment it contains; it is of itſelf eaſy of digeſtion, and fits light on a delicate ſtomach, provided it is taken without heavy ſauces, or preparations of butter.

It is the opinion of ſome writers, that animal diet has conſiderable influence on the powers of the underſtanding, being equally adverſe to the exertions of genius, ſentiment, and delicate feelings, as well as to deep mental reſearches. Dr. Falconer, after expreſſing this opinion reſpecting the influence of animal diet, adds, at the ſame time, that it may, nevertheleſs, be better adapted to the common buſineſs of life,

life, than a diet which produces a greater degree of ſenſibility. On the contrary, in proof of the favourable nature of vegetable diet to mental exertion, he quotes the anecdote related by Cheyne of ſir Iſaac Newton, who was ſo ſenſible of the unfavourable operation of animal food, that during the time of writing his treatiſe on optics, which is generally thought to be the work in which his genius diſplayed itſelf in its fulleſt force, he lived on a vegetable diet only, and that extremely ſimple and rigid. There is, doubtleſs, ſome truth in theſe obſervations; but the extreme temperance, and not the vegetable nature of the food, may be conſidered as the favourable meaſure. We are ſatisfied that, after a temperate meal, even of animal food, the mind is ſoon again adequate to its beſt exertions.

In reſpect to vegetables, the beſt rule is to uſe thoſe which beſt agree with each particular conſtitution. All the vegetables brought to table, which have been rendered ſoft by boiling, are readily digeſtible. The raw vegetables, uſed in ſallad, &c., are ſomewhat leſs ſo; but, except where the ſtomach is much diſpoſed to aceſcency, they are generally wholeſome. "On this head," ſays Dr. Fothergill, "I have only one ſhort caution to give. Thoſe who think it neceſſary to pay any attention to their health at table, ſhould take care that the quantity of bread, and of meat, and of puddings, and of greens, ſhould not compoſe each of them a meal, as if ſome were only thrown in to make weight; but carefully to obſerve, that the ſum of all together do not exceed due bounds, or incroach upon the firſt feelings of ſatiety."

With reſpect to fruit, it is, doubtleſs, wholeſome, in its ripe ſtate; eſpecially, if taken in the forenoon, or inſtead of a meal. But, like other agreeable and nutritious ſubſtances, it muſt prove injurious, when added to the load of the ſtomach, after a plentiful meal.

Much might be ſaid about the comparative advantages of the different kinds of liquor uſed at table. The great object of drink at our meals is to dilute the aliment taken into the ſtomach, and thus render it more capable of digeſtion. It is too often, however, uſed for a very different purpoſe; namely, to ſtimulate an imperfect appetite, and to enable the ſtomach to receive with reliſh what, in its unſtimulated ſtate, it would loath and reject. In as much, then, as drink is conducive to exceſs in eating, it is pernicious to take large and frequent draughts of any liquid during the great meal. It will be ſeen, under the article CORPULENCY, how little liquid is abſolutely required by nature for the healthy digeſtion, and how much a free uſe of the mildeſt and moſt unexceptionable tends to promote corpulency, by promoting gluttony. Dr. Fothergill has laid down a few ſimple rules in reſpect to drink.

"The leſſer quantity of fermented liquors we accuſtom ourſelves to the better.

"To abſtain from ſpirits of every kind, however diluted, as much as may be.

"Where mild, well-brewed beer agrees, to keep to it as a beverage.

"Where water does not diſagree to value the privilege, and continue it.

"Like what has been ſaid of diet in general, ſo, likewiſe, it may be added in reſpect to liquors; it is the quantity, in common, that does more harm than the kind; and people, eſpecially in the fore part of life, cannot be too ſolicitous to ſhun the firſt temptations to the love of ſpirituous liquors." Loc. cit.

Thus alſo the nonagenarian Dr. Heberden. "Potui aptiſſimæ ſunt cereviſia tenuis, et aqua pura. Spiritus, qui vocatur vini, et vinum aqua mixtum, cane pejus et angue ſunt vitanda. Etenim plures cognovi, qui horum uſu ſenſim ſeſe aſſuefecerunt ſiquoribus vinolentis, quibus iiidies meracioribus ſumptis brevi omnino carere non potuerunt, donec ex ſobriis et ſanis facti ſunt ebrioſi et valetudinarii; tam animorum, quam corporum debilitate, graviſſimas hujus erroris pœnas luentes." Comment. loc. cit.. See DRUNKENNESS.

There is another repaſt which, ſince the introduction of tea, is become a kind of neceſſary of life, and is as much expected in every family as the other uſual meals themſelves. Upon the ſubject of tea and coffee, eſpecialry when taken after dinner, much difference of opinion prevails. Some have conſidered tea as invariably noxious, but from oppoſite cauſes; one aſſerting that it is noxious only when the infuſion is weak, another when it is ſtrong; the former attributing its pernicious effects to the hot water alone, the latter to the narcotic quality of the tea. The laſt opinion is, we believe, in a certain degree, correct. There is unqueſtionably in a ſtrong infuſion of tea a quality, which excites diſorder of the ſtomach, head-ache, &c. in numerous individuals, and which, taken plentifully and late, will altogether prevent ſleep for many hours, in ſtill greater numbers. But the notion of the warm water relaxing and enfeebling the ſtomach, is probably deduced, erroneouſly, from the effects of warm water on inanimate ſubſtances, and from the ſoddening of the cuticle after long immerſion in it. Warm water is doubtleſs a gentle *ſtimulus* to the ſtomach, and has been recommended, alone, for that purpoſe, to invalids ſuffering under dyſpepſia, or indigeſtion. (See Saunders on the Liver.) In this view, then, a warm watery liquid may be uſeful to the digeſting ſtomach; and farther by diluting its contents, it muſt facilitate the motions and commixture of them, and therefore tend to expedite the proceſs of digeſtion. Hence tea, not too ſtrong, taken an hour or two after the meal of dinner, is, in our opinion, a ſalutary repaſt. And it is well known that, among perſons of weak digeſtive organs, the oppreſſion of ſtomach, occaſioned by even a temperate meal, is ſpeedily removed after drinking tea. According to this view of the matter, however, the leſs that is eaten with it, the better; for either ſweet cakes, or cakes of any kind, eſpecially with butter, muſt rather retard digeſtion than promote it. For, if whilſt the ſtomach is performing its taſk, a ſecond quantity of food is added, although of a lighter quality, the whole maſs is augmented, and as the additional matter muſt be aſſimilated to the chyle, now forming, the work of digeſtion is impeded.

The imagination of ſome phyſicians has wandered far to deſcribe the miſchiefs of this ſuppoſed enervating liquor, tea; and they would repreſent the picture as truly alarming. "Tea," ſays a ſenſible popular writer, "will induce a total change of conſtitution in the people of this country. Indeed it has gone a great way towards effecting that evil already. A debility, and conſequent irritability of fibre, are become ſo common, that not only women, but even men are affected with them. That claſs of diſeaſes, which, for want of a better name, we call nervous, has made almoſt a complete conqueſt of the one ſex, and is making haſty ſtrides towards vanquiſhing the other." (Buchan.) It has been frequently aſſerted by others, that the diſeaſes of this country have undergone a great change ſince the days of Sydenham, from the ſame cauſe, and inſtead of highly inflammatory fevers, we now ſee thoſe only of the low kind, accompanied by debility. This degeneration is, perhaps, not leſs fanciful, than that of the heroes of Homer and Virgil. Sydenham has deſcribed a moſt ample catalogue of nervous diſorders under the head of hypochondriaſis; and the meaſles and ſmall-pox are juſt as inflammatory now, as in the time of that able phyſician. Or if a change be admitted to have

have occurred in our conſtitutions, it may be as juſtly attributed to other changes in the mode of life, as to the ſipping of tea; to the increaſe of luxury in every rank, and every department of life.

In a ſtate of actual diſeaſe, and eſpecially in febrile complaints, a certain degree of caution is requiſite; but not ſo much, perhaps, as is often preſcribed. For, in the febrile ſtate, the ſtomach naturally loathes animal food, and is averſe in the extreme to the ſtronger and more alkaleſcent kinds, which it cannot be forced to take without much oppreſſion, and increaſe of the diſeaſe: but in the decline of the fever, the ſick often crave the lighter ſorts of animal food, and uſe them with impunity. In this point, however, the feelings of the patient ſhould be ſpecially conſulted; for, too often, the officiouſneſs and miſtaken kindneſs of nurſes and friends miſlead the patient; they preſs upon him articles, which his own inſtinctive ſenſations would not have led him to deſire, and which, therefore, injure him. The lower claſſes, from among whom our nurſes are of courſe choſen, are with difficulty reſtrained from pouring in wine and other ſtimulants, in every ſtage of febrile diſeaſes, from a notion that the patient will die for want of nouriſhment, as they cannot eat, unleſs ſomething comfortable is given.

Febrile thirſt is moſt effectually removed by ſimple water; whether it be cold or tepid is perhaps of little importance; and in general as much ought to be given as is agreeable to the ſick. Various forms of diluent drink, in which the properties of the water are ſcarcely changed, except in its flavour, may be uſed; ſuch as water in which currant-jelly, and various ſyrups, have been mixed, or tamarinds, roaſted apples, ſage, balm, or other palatable ingredients.

In chronic diſeaſes, accompanied with hectic fever, it is important to ſupport the ſtrength of the body, without ſtimulating the arterial ſyſtem; that is, by adminiſtering a diet, which is at once nutritious, and eaſy of digeſtion. For this purpoſe, a diet conſiſting chiefly of milk, with vegetables, and diluent drinks, is generally recommended. The milk of the aſs and the goat, which contain a larger proportion of ſugar, and leſs of the butyraceous and caſeous matter than cow's milk, and therefore are equally or more nutritive, and occaſion leſs excitement during the proceſs of digeſtion, are frequently preferred. But cow's milk may be eaſily rendered more ſaccharine or leſs caſeous by art, and its qualities appoſitioned to the powers of the ſtomach. A ſtrict perſeverance in a diet of this nature, and a rigid rejection of every thing ſtimulating, liquid or ſolid, is in many chronic diſeaſes the moſt valuable courſe of medicine, as it ſupports the conſtitution, without augmenting the diſeaſe, as a heating diet would do, and thus often affords the powers of the conſtitution an opportunity of reſtoring its own health, or removes all impediment to the operation of medicines.

The effects of a diet of animal matters excluſively, in removing the leading ſymptoms, if not in curing the diſtreſſing and generally fatal diſeaſe, the DIABETES *mellitus*, has been ſtrongly exhibited by Dr. Rollo; and it cannot be doubted that this diet has a much greater power over the ſymptoms of this obſcure malady, than all the medicines which have as yet been adminiſtered for its cure. See DIABETES.

As the gout, apoplexy, palſy, lethargy, and other diſeaſes of a full habit, ariſe from too great a quantity of blood, or of fat, &c. in the ſyſtem, a rigid temperance in diet is the moſt effectual and unexceptionable mode of preventing and of removing the prediſpoſition to theſe diſeaſes. Dr. Gregory, the preſent profeſſor of the practice of phyſic at Edinburgh, affords an animating example of the effect of ſtrict temperance, with corporeal exerciſe, in completely baniſhing the gout from the conſtitution, although he had it hereditarily from both parents, and ſuffered ſome ſevere attacks at an early period of life. In the inſtance of the miller of Billericay, we have a ſtill more ſtriking inſtance of the benefits derived from a proper change of diet, to the loweſt degree of abſtinence, in removing enormous corpulence, and all its attendant ſymptoms of diſeaſe (See CORPULENCY.) In fact, much of the adminiſtration of medicines might be ſuperſeded, would mankind ſubmit their appetites in a ſomewhat greater degree to the controul of reaſon; and Dr. Cheyne's obſervation is very juſt. Any one, he ſays, may loſe a pound of blood, take a purge, or a ſweat, by dropping the great meal, or by abſtaining from animal food, or fermented liquors for four or five days, as effectually as by opening a vein, ſwallowing a doſe of pills, or taking a ſudorific bolus. Eſſay on Health, p. 35.

The diet of infants and children ſhould be regulated with great attention. Many an infant is loſt in conſequence of improper food; for a ſtate of irritation in the ſtomach and inteſtines, occaſioned by crude and ill-digeſted aliment, is one of the moſt prolific ſources of convulſions in the early periods, and of maraſmus and tabes afterwards. Here, as in moſt other points, we chiefly err, by neglecting the intimations of nature. The proper food for infants is pointed in the milk of the parent, and, therefore, in our attempts to ſubſtitute a diet, when that is not to be procured, or is not in ſufficient abundance, it behoves us to imitate the food of nature.

DIET-*Drinks*, a form of phyſic, including all the medicated wines, wheys, and ales, uſed in chronic caſes. They require a courſe or continuance to anſwer any intention of moment. In acute caſes they are of no uſe; but where the diſorder of the conſtitution is gradually to be gained upon, much help may be had from them.

DIET, or *Dyet*, is alſo uſed for an aſſembly of the ſtates or circles of the empire, or Poland, to deliberate and concert meaſures for the public good.

The general diet of the empire is ordinarily held at Ratiſbon. It conſiſts of the emperor in perſon, or by his repreſentative or commiſſary; the nine electors, three of whom are eccleſiaſtic, and the other ſix ſecular, forming the electoral college; the eccleſiaſtical princes, *viz.* archbiſhops, biſhops, abbots, and abbeſſes, and the ſecular princes, forming the ſecond college; and the repreſentatives of the imperial cities, who conſtitute the third college, and are divided into two benches, *viz.* that of Suabia and of the Rhine. This diet has been uſually ſummoned by the emperor, but there are ſome caſes in which the electors have ſummoned it without his conſent, or requeſted him to ſummon it. In the abſence of the emperor the right of convocation belongs to the king of the Romans. The diet makes laws, raiſes taxes, determines differences between the ſeveral princes and ſtates, and relieves the ſubjects from the oppreſſions of their ſovereigns. The diets of the empire were originally the ſame with aſſemblies of March and May, held by the kings of France: they met, at leaſt, once a year; and every freeman had a right to be preſent. Theſe were aſſemblies, in which the monarch deliberated with his ſubjects, concerning their common intereſt: but when the princes, dignified eccleſiaſtics, and barons, acquired territorial and independent juriſdiction, the diet became an aſſembly of the ſeparate ſtates, which formed a confederacy of which the emperor was the head. Whilſt the conſtitution of the empire remained in its primitive form, the ſeveral members of the diet were obliged to attend in perſon, otherwiſe he not only loſt his vote, but was liable to a heavy penalty. When the members of the diet became independent ſtates, the right of ſuffrage was annexed to the territory or dignity, not to the perſon; and the members might ſend their deputies,

as

as princes ſend ambaſſadors. By degrees any member, who poſſeſſed more than one of thoſe ſtates or characters, which entitle to a ſeat in the diet, was allowed a proportionable number of ſuffrages. The Imperial cities alſo, as ſoon as they became free and acquired independent juriſdiction, were received as members of the diet. The powers of the diet extend to every thing relative to the common concern of the Germanick body, or that even intereſt or affect it as a confederacy. The diet takes no cognizance of the inferior adminiſtration in the different ſtates, unleſs that happens to threaten or diſturb the general ſafety. Robertſon's Hiſt. Charles V. vol i. p. 462.

The term diet is alſo applied to the aſſembly of electors for the choice of an emperor or king of the Romans: this is uſually held at Frankfort on the Main.

The general diet of Poland was by the laws only to be held every two years; but preſſing occaſions convened them every year; the laws alſo confined their ſitting to fifteen days, but they frequently protracted it to ſix weeks. The uſual place was at Warſaw, the capital of the kingdom; though it has been often held at other places: in effect, as by the laws every third diet was to be convened at Grodno, in Lithuania; whenever, for particular reaſons, it was judged meet to change the order, and hold it elſewhere, the nobility of the grand duchy muſt have conſented to it. It was the king who fixed the time, and ſummoned it by circulars letters ſent to all the palatines. In an interregnum the archbiſhop of Gneſna called the diet.

The ſeveral particular diets, which were held ſix weeks before the general one, ſent three deputies each, choſen out of the members thereof.

In Poland there were likewiſe diets on horſeback, held in the champagne, or country, ſuch were thoſe wherein they choſe their king. They were called poſpolites. See POLAND.

There are likewiſe diets held in Switzerland; diets of the Proteſtant cantons; diets of the Catholic cantons; and general diets. The firſt aſſemble at Araw, and are convoked by the canton of Zurich; the ſecond at Lucern, convoked by the canton of that name; the third, compoſed of the deputies of all the cantons, both Proteſtant and Catholic, is held twice a year, at the end of June, and the beginning of December, and meets at Baden. It is the canton of Zurich which has the right of convening it. See SWITZERLAND.

DIETA, in our *Old Law Books*, denotes a day's journey. "Omnis rationabilis dieta conſtat ex viginti milliaribus." Fleta.

DIETERSTORFF, in *Geography*, a town of Germany, in the archduchy of Auſtria; four miles S.S.W. of Tuln.

DIETETIC, DIÆTETICA, that part of phyſic which conſiders the way of living, with relation to food, ſuitable to particular caſes. See DIET.

DIETFURTH, in *Geography*, a town of Germany, in the centre of Bavaria, ſituated on the north ſide of the Altmuhl; 19 miles weſt of Ratiſbon.

DIETHUSA, in *Ancient Geography*, an iſland of the Ægean ſea; repreſented by Pliny as a deſerted iſland.

DIETMANFRIED, in *Geography*, a town of Germany, in the circle of Swabia, belonging to the abbey of Kempton; eight miles N.N.W. of Kempton.

DIETRICH, or DIETRICY, CHRISTIAN WILLIAM ERNEST, in *Biography*, a painter and engraver of conſiderable merit, was born at Weimar in 1712, and reſided chiefly at Dreſden, where he was profeſſor of the academy of arts. As a painter he poſſeſſed extenſive abilities, and ſucceeded both in hiſtory and landſcape. He alſo engraved a great number of ſmall ſubjects from his own compoſitions, in the ſtyle of Oſtade, of Laireſſe, and of Salvator Roſa. Several of theſe etchings are very rare. A print by this maſter of a "Satyr entertained by a Peaſant and his Family," is finely drawn and admirably executed: it is dated 1739. The time of his death is not aſcertained. Strutt.

DIETRICHSTEIN, in *Geography*, a ſmall town of Auſtria, in Upper Carinthia, belonging to the prince of Dietrichſtein. It is ſituated on the river Geyl, three miles weſt of Arnoldſtein.

DIETTER, CHRISTIAN LUDWIG, in *Biography*, born at Ludwiſburg, 1757, performer on the violin, compoſer, and maitre de chapelle to the duke of Wirtenburg, at Stuttgard. He was one of the firſt ſcholars of his ſerene highneſs's academy, where he at firſt ſtudied painting, and had the opportunity of hearing lectures in mythology, hiſtory, and geography; but devoted all his leiſure hours to muſic. The duke, obſerving his muſical talents, adviſed him to cultivate them excluſively. He accordingly ſtudied under Schubart, and the celebrated violiniſt, Celeſtini, who came from Rome to England with the late duke of Dorſet, and after remaining in London ſeveral years, went to Stuttgard, where he was placed at the head of the opera-band. Ditter, whoſe thirſt for knowledge was inſatiable, wiſhing to ſtudy the theory of muſic regularly, and finding that he could get no inſtructions from the maeſtro di cappella Bononi, ſtudied the works of Jomelli, and other famous compoſers; and in the year 1778 gained a prize medal for compoſition, which he had gained two years before on the violin. He continued to reſide in the duke's academy, or conſervatorio, till the year 1781, and compoſed various works for the theatre as well as for public concerts.

DIETZ, in *Geography*, a ſmall town of Germany, in the circle of the Upper Rhine, on the river Lahn, formerly the capital of the principality of Naſſau Dietz, and as ſuch belonging to the prince of Orange, but ſince the peace of Tilſit, in the conſcription of the new kingdom of Weſtphalia. It is 18 miles E. of Coblentz, 30 N. of Mayence. Lat. 50° 22'. See NASSAU.

DIEU, LEWIS DE, in *Biography*, an eminent proteſtant divine, was born at Fluſhing about the year 1590, where he afterwards became paſtor to the French church. He was an uſeful and popular preacher, and might have been appointed court miniſter at the Hague, an honour which he declined, though preſſed upon him by prince Maurice of Orange, who had heard him preach at Zealand. In 1619, he was appointed aſſiſtant to his uncle at the Walloon college at Leyden; the duties of this ſituation he performed with diligence and credit, until his death, which happened in the year 1642. His publications were moſtly theological; ſuch as "A Commentary on the Four Goſpels;" "Notes on the Acts of the Apoſtles;" &c. &c. M. Bayle has given the titles of a long liſt of works, which he publiſhed during his life, or which were given to the world ſoon after his deceaſe. By them it ſhould ſeem that he was a learned and very reſpectable divine. Bayle. Moreri.

DIEU, *l'Ile*, or *l'Ile d'Yeu*, in *Geography*, a ſmall iſland on the weſtern coaſt of France, 9 miles S.W. of Saint Jean de Mont, and 15 W. of Saint Gilles. W. long. 2° 10'. N. lat. 46° 50'. It is a rock of granite, of a ſuperficies of nearly four miles, covered with a very thin ſoil of a ſandy earth, the produce of which is hardly ſufficient for the conſumption of its inhabitants for the ſpace of three or four months. The paſtures are ſo ſcanty, that they feed only a very few cows and ſheep. The women till the ground, moſt of the men being engaged as ſailors and fiſhermen. There is one ſmall town, the harbour of which is inconvenient, and incapable of being fitted for trade. The whole iſland contains ſix ſquare leagues, or 27,600 French arpens. It forms a canton of the

the diſtrict of the Sables d'Olonne, in the department of La Vendée. The town has 1049 inhabitants. The whole canton or iſland has two communes, and 2053 inhabitants. Herbin. Statiſtique de la France.

Dieu-le Fit, a ſmall town of France, in the department of the Drôme, chief place of a canton in the diſtrict of Montelimart, 15 miles E. of that place. It has ſome mineral ſprings, one of which is particularly remarkable for the great quantity of native vitriol which its water contains. This water, taken inwardly, is an excellent remedy againſt thoſe diſeaſes of the eyes which require tonics; it diſſipates inflammation, ſtrengthens the ſight, and cures beſides all cutaneous diſeaſes, and long-ſtanding ulcers.

The population of Dieu-le-Fit amounts to 2847 individuals. The canton contains, upon a territorial extent of 330 kiliometres, 16 communes, and 8636 inhabitants.

Dieu *& mon droit, q d. God and my right*, the motto of the arms of England, firſt given by king Richard I. to intimate, that he held not his empire in vaſſalage of any mortal.

It was afterwards taken up by Edward III. when he firſt claimed the crown of France; and it was continued, without interruption, to the time of king William III. who uſed the motto *Je maintiendray;* though he commanded the former to be retained on the great ſeal. The ſame is to be underſtood of the late queen Anne, who uſed the motto *Semper eadem;* which had been before uſed by queen Elizabeth.

Dieu *ſon act*, in *Law*, are words often uſed in our old law; and it is a maxim in law, that the act of God ſhall prejudice no man. Therefore, if a houſe be blown down by a tempeſt, thunder, or lightning, the leſſee or tenant for life or years, ſhall be excuſed in waſte. Likewiſe he hath by the law a ſpecial intereſt to take timber to build the houſe again for his habitation. (4 Rep. 63. 11 Rep. 82.) So when the condition of a bond conſiſts of two parts in the disjunctive, and both are poſſible at the time of the obligation made, and afterward one of them becomes impoſſible by the act of God, the obligor is not bound to perform the other part. (5 Rep. 22.) And where a perſon is bound to appear in court at a certain day, if before the day he dieth, the obligation is ſaved, &c. See Bond.

DIEUE, in *Geography*, a town of France, in the department of the Meuſe, and diſtrict of Verdun, on the Meuſe; ſix miles S. of Verdun.

DIEULISH, a river of England, which runs into the Stour, near Sturminſter, in Dorſetſhire.

DIEULOWARD, a town of France, in the department of the Meurte, on the Moſelle, and diſtrict of Pont-a-Mouſſon; three leagues N. N. W. of Nancy.

DIEUPART, Charles, in *Biography*, we believe, was a native of France, but who had reſided ſo long in England, that his name only ſuggeſted the idea of his not being an Engliſhman. We have been informed, by thoſe who remembered him, that he was a correct and firm performer on the violin, and aſſociated with Clayton, and Nicola Haym, as leader of the band at Drury-lane and Dorſet-gardens, in the firſt attempts at operas, after the Italian manner. Dieupart, conſequently, played the firſt violin in the operas of Arſinoe, and Camilla, when they were performed in 1705, entirely in Engliſh; and in 1707, in Addiſon's Roſamond, ſet by Clayton. But on the arrival of Valentini, when operas were performed half in Engliſh, and half in Italian; and in 1710, on the arrival of Nicolini and Handel, Clayton, Haym, and Dieupart, diſcouraged from any further attempts at operas by Engliſh performers, were obliged to ſolicit the encouragement of the public in eſtabliſhing a concert, which they propoſed to carry on jointly at Clayton's houſe, in York buildings, where there was a large room, which had long been appropriated to concerts. The propoſals for this undertaking are inſerted in two letters printed in the Spectator, N^os^ 258 and 278. This aſſociation continued but a ſhort time; for, in 1711, we find Clayton engaged with ſir Richard Steele, in a ſubſcription at York buildings. Haym went to the Haymarket, became a performer in the opera band, was frequently the opera poet, and ſometimes the compoſer; while Dieupart betook himſelf to teaching the harpſichord, and was admitted in that capacity into ſome of the beſt families in the kingdom: but late in life, he degenerated into negligence and a vulgar taſte; leading low concerts at ale-houſes in obſcure parts of the town, where he won all hearts by his neat and elegant manner of playing Corelli's ſolos, which he might have done in better company, if, like poor Smart the poet, he had not, during his derangement, preferred foul linen to clean. Dieupart had a great paſſion for diſguiſing himſelf like a common fidler, and playing in booths at fairs. The late Mr. Naphthali Frankes (a firſt rate dilettante on the violin) found him out at May fair in that capacity, by his ſtyle of playing, in which he did not remember to diſguiſe his bow, his tone, or his taſte. He died about the year 1740 at a great age, and in very indigent circumſtances. We find in the Dutch catalogues of the time, ſix ſets of harpſichord leſſons by Dieupart, which he afterwards transformed into concertos for the violin, flute, baſe-viol, and arch lute.

DIEUZE or Dieuse, in *Geography*, a ſmall town of France, in the department of the Meurthe, chief place of a canton in the diſtrict of Chateau Salins, ſituated on the river Seille, between Metz and Saverne, ſix miles E. of Marſal, and 27 N. W. of Nancy. Lat. 48° 50′. It has the richeſt ſalt ſprings in France. Their annual produce averages 256,908 French quintaux.

Dieuze contains 3344 inhabitants. The canton reckons 10,050, diſtributed in 24 communes, upon a territorial extent of 187½ kiliometres. Herbin Statiſtique de la France.

DIEXAHÆDRIA, in *Natural Hiſtory*, the name of a genus of ſpars. The word is derived from the Greek δις, *twice*, εξ, *ſix*, and εδρα, *ſide*. The bodies of this genus are ſpars, compoſed of twice ſix planes, being formed of two hexædral pyramids, joined baſe to baſe, without any intermediate column. Of this genus there are only two known ſpecies: 1. One with long, narrow, and ſharp-pointed pyramids, found in Lamb's-cave on Mendip hills: and, 2. One with long, broad, and obtuſe pyramids: this is found in the mine of Goſſelar in Saxony, and in many of the mines of the Hartz Foreſt. Hill's Hiſt. of Foſſils, p. 213.

DIEXODUS, Διεξοδος, in *Rhetoric*, is uſed for *digreſſion*, which ſee.

DJEZAN, in *Geography*, a ſea-port of Arabia, ſituated on a cape of the Red ſea, which forms one ſide of a large bay, in N. lat. 16° 45′. It is built, like other towns, on the coaſt, with ſtraw and mud. It was once a conſiderable place for trade, but ſince coffee hath been ſo much in demand, of which they have none, that commerce is removed to Loheia and Hodeida. It is an uſurpation from the territory of the Imam, by a ſheriff of the family of Beni-Haſſan, called "Bovariſh." The inhabitants, ſays Bruce, are all ſheriffs, in other terms, troubleſome ignorant fanatics. This town is peculiarly ſubject to fevers. The *faunteit*, ſignifying Pharaoh's worm, or worm, is very frequent here. The place abounds with excellent fiſh, and fruit which is brought from the mountains, whence they are alſo ſupplied with very good water.

DIEZE Maxime of Rameau, in *Muſic*, is an interval

whoſe ratio is $\frac{243}{250}$, or $25\Sigma + f + 2m$, which is the SEMITONE *ſubminimis*, which ſee.

DIEZE *Major* of Rameau, is an interval whoſe ratio is $\frac{125}{128}$, or $21\Sigma + 2m$, which is the *enharmonic* DIESIS, which ſee.

DIEZE *Minor* of Rameau, is an interval whoſe ratio is $\frac{3072}{3125}$, or $15\Sigma + f + m$, which is the HYPEROCHE, which ſee

DIEZE *Minime* of Rameau, is an interval whoſe ratio is $\frac{196883}{200000}$, or $14\Sigma + f + m$; its common logarithm is .9930612 9682. It reſults from the addition of the following intervals, *viz.* a diaſchiſma and a minor reſidual: a major comma and a medius reſidual; alſo as the difference of the following intervals, *viz.* a ſchiſma from an hyperoche; a major comma from a ſemitone ſubminimis; and a ſemitone minimum from a limma; alſo a major third and five minor thirds from four minor fourths, which laſt gives a practical method of tuning the dieze minime on an organ, &c.

DIFF, is the name of an inſtrument of muſic among the Arabs, ſerving chiefly to beat time to the voice: it is a hoop, ſometimes with pieces of braſs fixed to it to make a jingling, over which a piece of parchment is diſtended. It is beat with the fingers, and is the true tympanum of the ancients. Ruſſell's Hiſt. of Aleppo, p. 94.

DIFFARREATION, among the Romans, a ceremony whereby the divorce of their prieſts was ſolemnized.

The word comes from the prepoſition *dis*; which is uſed in compoſition, for diviſion, or ſeparation; and *farreatio* a ceremony with wheat, of *far*, wheat.

Diffarreation was properly the diſſolving of marriages, contracted by confarreation; which were thoſe of the pontifices, or prieſts. Feſtus ſays, it was performed with a wheaten cake. Vigenere will have confarreation and diffarreation to be the ſame thing.

DIFFERENCE, in *Logic*, an eſſential attribute belonging to ſome ſpecies, and not found in the genus; being the idea that defines the ſpecies.

Thus, body and ſpirit are the two ſpecies of ſubſtance, which in their ideas include ſomething more than is included in the idea of ſubſtance. In body, for inſtance, is found impenetrability, and extenſion; in ſpirit, a power of thinking, and reaſoning: ſo that the difference of body is impenetrable extenſion, and the difference of ſpirit is cogitation.

DIFFERENCE, in *Mathematics*, the exceſs of one quantity above another.

When a leſs quantity is ſubtracted from a greater, what remains is called the difference.

It was a fundamental principle among the ancient geometers, that the difference of any two unequal quantities, by which the greater exceeds the leſſer, may be added to itſelf, till it ſhall exceed any propoſed finite quantity of the ſame kind. This principle ſeems inconſiſtent with the ſuppoſition of an infinitely ſmall quantity or difference, which added to itſelf any number of times, is never to be ſuppoſed to become equal to any finite quantity whatſoever; which is the foundation of the modern method of infiniteſimals. However, this laſt may, with proper caution, be made uſeful and accurate.

DIFFERENCE *of longitude* of two places, is an arch of the equator intercepted between the meridians of the places.

DIFFERENCE, *Aſcenſional*, in *Aſtronomy*. See ASCENSIONAL.

DIFFERENCES, in *Heraldry*, certain additaments to coat-armour; whereby ſomething is altered, or added, to diſtinguiſh the younger families from the elder, or to ſhew how far they are removed from the principal houſe. They are called, in Latin, diminutiones, and diſcerniculæ armorum; and, by the French, briſures.

Of theſe differences Sylv. Morgan gives us nine, which obtain principally among us: *viz.* the label, which denotes the firſt and eldeſt ſon; the creſcent, the ſecond; the mullet, the third; the martlet, the fourth; the annulet, the fifth; the fleur-de-lis, the ſixth; the roſe, the ſeventh; the croſs-moline, the eighth; and the eight-foil, the ninth. See each under its proper article.

Again, as the firſt differences are ſingle for the ſons of the firſt houſe, or deſcent; the ſons of the younger houſes are differed by combining or putting the ſaid differences upon each other. As the firſt differences are, the label, creſcent, &c. for the firſt houſe; the difference for the ſecond houſe is the label on a creſcent, for the firſt of that houſe, during his father's life only; for the ſecond, a creſcent charged with a creſcent; for the third brother of the ſecond houſe, a mullet on a creſcent, &c. Siſters, except of the blood-royal, have no other mark of difference in their coats of arms beſides the form of the eſcutcheon. See LOZENGE.

The original of differences is controverted. Camden will have them to have begun about the time of king Richard I. Paradin aſſigns differences worn as early as the year 870. The preſident Fauchet obſerves differences to have been hereditary in the French families before the time of Louis le Gros, who came to the crown in the year 1110. Moreau refers them to the time of St. Louis; and Lallonette, Belleforeſt, &c. to that of Philip Auguſtus. The occaſion of their riſe is well accounted for by Colombiere.

All nations, ſays he, prefer the eldeſt brothers to the younger; whence thoſe, in a direct line, ſucceeding to their fathers, and becoming maſters of their lands, took on them their coat-armour, without any change, or alteration; and tranſmitted the ſame again to their eldeſt ſons; the younger brothers, or baſtards, not being allowed to bear the ſame arms, without ſome additional mark, to diſtinguiſh them from the elder. Hence ſome heralds, he goes on, have endeavoured to confine them to certain fixed and determinate figures, for diſtinguiſhing the ſecond from the firſt, the third from the ſecond, and ſo on to the ſixth; aſſigning the ſecond a label, the third a bordure, the fourth an orle, the fifth a battoon, and the ſixth a bend or cottice. And the deſcendants of theſe bear double differences, or differences charged on one another; *viz.* the eldeſt ſon of the ſecond ſon to retain his paternal coat, with the difference of the label of three points; the ſecond, the label of four points; the third, ſuch a label on a chief; the fourth, a label charged with certain figures, as eaglets, lioncels, martlets, creſcents, roſes, &c. And, for the ſame reaſon, the ſecond ſon of the third ſon ſhall bear a bordure engrailed; the third, a bordure charged with bezants, or tourteaux, &c.

But the ſame author judges the fixing any certain invariable differences at all an abuſe; becauſe they may happen not to be agreeable to the paternal coat, but very much deface and blemiſh it. He adds, that many other figures, beſide thoſe above-mentioned, may be uſed as differences; as ſhells, bezants, cinquefoils, and a thouſand more. Some younger families have made the difference in their arms by only diminiſhing the ordinaries, or changing the poſture; and others, by only changing the metal, or colour.

It muſt be added, that the difference may be of metal on metal, or colour on colour; which, in other caſes, is falſe heraldry.

DIFFERENCES, *Ancient*. See BORDURES.

DIFFERENTIAL, DIFFERENTIALE, in the *Higher Geometry*, an infinitely ſmall quantity, or a particle of quantity ſo ſmall as to be leſs than any aſſignable one. See FLUXION.

DIFFERENTIAL.

It is called a differential, or differential quantity, becauſe frequently conſidered as the difference of two quantities; and, as ſuch, it is the foundation of the differential calculus. Sir Iſaac Newton, and the Engliſh, call it a moment, as being conſidered as the momentary increaſe or decreaſe of a variable quantity. Mr. Leibnitz, and others, call it alſo an infinitesimal. See INFINITESIMAL.

DIFFERENTIAL *of the firſt, ſecond, &c. degree.* See DIFFERENTIO-DIFFERENTIAL.

DIFFERENTIAL *calculus*, or *method*, is a method of differencing quantities; that is, of finding a differential, or infinitely ſmall quantity, which, taken an infinite number of times, is equal to a given quantity. See CALCULUS, DIFFERENTIAL *method*, and FLUXIONS.

DIFFERENTIO-DIFFERENTIAL *calculus*, is a method of differencing differential quantities.

As the ſign of a differential is the letter d prefixed to the quantity, dx is the differential of x; that of a differential of dx is ddx, and the differential of ddx is $dddx$, &c. ſimilar to the fluxions $\dot{x}$, $\ddot{x}$, $\dddot{x}$, &c.

Thus we have degrees of differentials.

The differential of an ordinary quantity is called a differential of the firſt order or degree, as dx; that of the ſecond degree, is an infinitesimal of a differential quantity of the firſt degree, as ddx; that of the third degree, is an infinitesimal of a differential quantity of the ſecond degree, as $dddx$, and ſo on.

The powers of differentials are differenced after the ſame manner as the powers of ordinary quantities: and, again, as compound differentials either multiply or divide each other, or are powers of differentials of the firſt degree; differentials are differenced after the ſame manner as ordinary quantities; and, therefore, the differentio-differential calculus is the ſame, in effect, with the differential, or the method of fluxions.

DIFFERENTIAL, in the *Doctrine of Logarithms*. Kepler calls the logarithms of tangents differentiales; which we uſually call artificial tangents. See LOGARITHM, MESO-LOGARITHM, and TANGENT.

DIFFERENTIAL *equation* is uſed by ſome mathematicians for an equation involving infinitesimal differences, or fluxions. Thus the equation $3x^2dx - 2axdx + aydx - 3y^2dy + axdy = 0$ in the foreign notation, or $3x\dot{x}\dot{x} - 2ax\dot{x} + ay\dot{x} - 3y^2\dot{y} + ax\dot{y} = 0$ in the Engliſh notation, is called a differential equation. But theſe equations ſhould, conſiſtently with the Engliſh, or ſir Iſaac Newton's notation, be rather called fluxional equations. Hence ſome of our mathematicians have applied the term differential equations in another ſenſe, to certain equations defining the nature of ſerieſes. See SERIES.

DIFFERENTIAL *method*, in *Mathematics*, an appellation given to a method of finding quantities by means of their ſucceſſive differences.

This method is capable of very extenſive application and uſe, in the conſtruction of tables, ſummation of ſerieſes, &c. It was firſt uſed, and the rules of it laid down, by Briggs, in his conſtruction of logarithms and other numbers, much in the ſame manner as they were afterwards taught by Cotes, in his "Conſtructio Tabularum per Differentias." See Briggs's Arithmetica Logarithmica, cap. 12, 13. and his "Trigonometria Britannica."

This method is given in another form by ſir Iſaac Newton in the fifth lemma of the third book of his Principia. He treats of it as a method of deſcribing a curve of the parabolic kind, through any given number of points: And he diſtinguiſhes two caſes of this problem; the firſt, when the ordinates, drawn from the given points to any line given in poſition, are at equal diſtances from each other; and the ſecond, when theſe ordinates are not at equal diſtances. He has given a ſolution of both caſes, but without demonſtration in that place, which has ſince been ſupplied by himſelf and others. See his Methodus Differentialis, publiſhed with other tracts of the ſame author, by Mr. Jones, London, 1711; and Stirling's Explanation of the Newtonian differential method, in the Phil. Tranſ. N° 362; Cotes, De Methodo Differentiali Newtoniana, in his works publiſhed by Dr. Smith; Herman, Phoronomia; and Le Seur and Jacquier, in their Comment on ſir Iſaac Newton's Principia.

It is to be obſerved, that the methods there demonſtrated, by ſome of theſe authors, extend to the deſcription of any algebraic curve through a given number of points, which ſir Iſaac, writing to Mr. Leibnitz, mentions as a problem of the greateſt uſe.

By this method, ſome terms of a ſeries being given, and ſuppoſed to be placed at given intervals, any intermediate term may be found nearly; and this therefore gives a method for interpolations. Briggs's Arith. Log. Newton Method. Differ. prop. 5. Stirling's Method. Diff.

Any curvilinear figure may alſo be ſquared nearly, of which ſome ordinates may be found. Newt. Meth. Diff. prop. 6. Cotes, ubi ſupra. Simpſon's Math. Diſſ. p. 115.

And this method may be extended to the conſtruction of mathematical tables by interpolation. Newt. Meth. Diff. in Schol. p. 100.

The ſucceſſive differences of the ordinates of parabolic curves, becoming ultimately equal, and the intermediate ordinate required, being determined according to ſir Iſaac's rules, by theſe differences of the ordinates, is the reaſon of this method being called the differential method. To be a little more particular.

The firſt caſe of ſir Iſaac's problem amounts to this: a ſeries of numbers, placed at equal intervals, being given, to find any intermediate number of that ſeries when its interval from the firſt term of the ſeries is given.

Subtract every term of the ſeries from the next following, and let the remainders be called firſt differences; then ſubtract each difference from the next following, and let theſe remainders be called ſecond differences; again let each ſecond difference be ſubtracted from the next following, and let theſe remainders be called third differences, and ſo on: then if A be the firſt term of the ſeries, d' the firſt of the firſt differences, d'' the firſt of the ſecond differences, d''' the firſt of the third differences, &c. and if x be the interval between the firſt term of the ſeries and any term ſought, E, that is, let the number of terms from A to E, both inclusive, be $= x + 1$, then will the term ſought,

$$E = A + \frac{x\,d'}{1} + \frac{x \cdot \overline{x-1}}{1 \cdot 2}\,d'' + \frac{x \cdot \overline{x-1} \cdot \overline{x-2}}{1 \cdot 2 \cdot 3}\,d''' + \frac{x \cdot \overline{x-1} \cdot \overline{x-2} \cdot \overline{x-3}}{1 \cdot 2 \cdot 3 \cdot 4}\,d'''' + \text{, \&c.}$$

which ſeries differs from the Newtonian in this, that the quantities $\frac{d''}{1 \cdot 2}$, $\frac{d'''}{1 \cdot 2 \cdot 3}$, $\frac{d''''}{1 \cdot 2 \cdot 3 \cdot 4}$ here uſed, ſignify the ſame with d'', d''', uſed by ſir Iſaac Newton.

Hence, if the differences of any order become equal, that is, if any of the quantities d'', d''', d'''', become $= 0$, we ſhall have a finite expreſſion for E, the term ſought; it being

ing evident, that the ſeries muſt terminate when any of the differences d'', d''', &c. become = 0.

It is alſo evident, that the coefficients $\frac{x}{1}$, $\frac{x \cdot \overline{x-1}}{1 \cdot 2}$, &c. of the differences, are the unciæ of the binomial theorem.

E. G. Suppoſe it were required to find the log. tangent of 5′, 1″, 12‴, 24⁗, or 5′, 1″, $\frac{62}{300}$, or 5′, 1″, 2066, &c.

Take out the log. tangents to ſeveral minutes and ſeconds, and take their firſt and ſecond differences, thus:

	Tang.	d'	d''	
5′ 0″	7.1626964			
		14453		
5 1	7.1641417		−49	
		14404		−48.
5 2	7.1655821		−47	
		14357		
5 3	7.1670178			

Here A = 7.164147; $x = \frac{62}{300}$; $d' = 14404$; and the mean ſecond difference $d'' = -48$. Hence

A - - - - -	7.1641417
$x\,d'$ - - - -	2977
$\frac{x}{1} \cdot \frac{x-1}{1} d''$ - - - - -	4
Therefore, the tangent of 5′, 1″, 12‴, 24⁗, is	7.1644398

A method may be deduced from the foregoing expreſſion, of finding the ſums of the terms of ſuch a ſeries. For if we imagine a new ſeries, whereof the firſt term ſhall be = 0, the ſecond = A, the third = A + B, the fourth = A + B + C, the fifth = A + B + C + D, and ſo on, it is plain that the aſſigning one term of this ſeries is finding the ſum of all the terms, A, B, C, D, &c. Now ſince thoſe terms are the differences of the ſums 0, A, A + B, A + B + C, A + B + C + D, and that by the ſuppoſition, ſome of the differences of A, B, C, D, &c. are = 0; it follows that ſome of the differences of the ſums will alſo be = 0; and that whereas in the ſeries $A + x\,d' + \frac{x \cdot \overline{x-1}}{1 \cdot 2} d''$, &c. by which a term was aſſigned, A repreſented the firſt term, d' the firſt of the firſt differences, and that x repreſented the interval between the firſt term and the laſt, we are to write 0 inſtead of A, A inſtead of d', d' inſtead of d'', d'' inſtead of d''', &c. and $x + 1$ inſtead of x, which being done, the ſeries expreſſing the ſums will be $0 + \frac{x+1}{1} \cdot$

$$A + \frac{\overline{x+1} \cdot x}{1 \cdot 2} d' + \frac{\overline{x+1} \cdot x \cdot \overline{x+1}}{1 \cdot 2 \cdot 3} d'' +, \text{ &c. or } x+1$$

$$\times A + \frac{x}{2} d' + \frac{x \cdot \overline{x-1}}{2 \cdot 3} d'' + \frac{x \cdot \overline{x-1} \cdot \overline{x-2}}{2 \cdot 3 \cdot 4} d''', \text{ &c.}$$

Or, again, if the real number of terms of the lines be called z, that is, if $z = x + 1$, or $z - 1 = x$, we ſhall have

$$\text{the ſum of the ſeries} = z \times A + \frac{z-1}{2} d' + \frac{\overline{z-1} \cdot \overline{z-2}}{2 \cdot 3} d'' + \frac{\overline{z-1} \cdot \overline{z-2} \cdot \overline{z-3}}{2 \cdot 3 \cdot 4} d''' +, \text{ &c.}$$

See De Moivre, Doct. of Chances, p. 59, 60. Miſc. Analyt. p. 153. Simpſon's Eſſ. p. 95.

For inſtance, let it be required to find the ſum of ſix terms of a ſeries of the ſquares of the natural numbers 1 + 4 + 9 + 16 + 25 + 36. Thus,

Terms.	d'	d''	d'''
1			
	3		
4		2	
	5		0
9		2	
	7		0
16		2	
	9		
25, &c.			

Here A = 1, $d' = 3$, $d'' = 2$, $d''' = 0$, and $z = 6$. The ſum conſequently will be

$$= z \times 1 + \frac{z-1}{2} \times 3 + \frac{\overline{z-1} \cdot \overline{z-2}}{2 \cdot 3} \times 2$$

$$= z \times 1 + \frac{3z-3}{2} + \frac{zz-3z+2}{3}$$

$$= z \times \frac{6 - 9 + 9z + 2zz - 6z + 4}{6}$$

$$= z \times \frac{1 + 3z + 2zz}{6} = \frac{z \cdot \overline{1+z} \cdot \overline{1+2z}}{6} = \frac{6.7.13}{6} = 91.$$

This eaſy example will be ſufficient to ſhew the applications of this rule. Thoſe who are deſirous of ſeeing its uſe in queſtions of chance, may conſult M. de Moivre's Doctrine of Chances, p. 59, ſeq. Various other inſtances of the uſe of this rule in finding ſums of progreſſions of figurative members, &c. may be ſeen in Miſc. Analyt. p. 154, ſeq.

As to the differential method, it is to be obſerved, that though ſir Iſaac and others have treated it as a method of deſcribing an algebraic curve, at leaſt of the parabolic kind, through any number of given points; yet the conſideration of curves is not at all eſſential, though it may help the imagination. The deſcription of a parabolic curve through given points, is the ſame problem as the aſſigning of quantities from their given differences, which may always be done by algebra, and by the reſolution of ſimple equations. See Mr. Stirling's Methodus Differentialis, p. 97. This ingenious author has treated fully of the differential method, and ſhewn its uſe in the ſolution of ſome very difficult problems. See SERIES.

DIFFERENTIAL *ſcale*, in *Algebra*, is uſed for the ſcale of relation ſubtracted from unity. See *Recurring* SERIES.

DIFFORM, DIFFORMIS, from *forma*, ſhape, is a word uſed in oppoſition to uniform; and ſignifies that there is no regularity in the form, or appearance, of a thing.

The botaniſts uſe it as a diſtinction of the flowers of ſeveral ſpecies of plants.

DIFFRACTION *of* LIGHT, is the bending of the rays of light, which is occaſioned by their paſſing by other bodies. Thus, if the light of the ſun be admitted through a hole in a room, otherwiſe darkened or cloſed, the image of the ſun within the room will be found to be larger than it ought to be, if the rays proceeded in ſtraight lines from the ſun to the ſcreen within the room. Alſo, if a hair, a wire, or other ſmaller body, be placed in the pencil of light which comes through the above-mentioned hole, the image of, or ſhadow of it, will be much larger than the hair or wire itſelf; which ſhews that the rays of light are bent in paſſing by the ſides of the hole, or of the hair, &c. This bending has been called diffraction; but more commonly INFLECTION *of Light*, which ſee.

DIFFUSE, DIFFUSIVE, is chiefly uſed for a proliх manner of writing, &c.

A dictionary cannot well be too diffuſive: for a man is never

never too much informed of the word he wanted; and he is not obliged to read that part of the explication which does not concern him.

A diffuſive ſtyle is proper for diſcourſes in the demonſtrative kind. Demoſthenes is cloſe, and conciſe; Cicero, on the contrary, is diffuſive.

DIFFUSE, in *Botanical Phraſeology*, is applied to the looſely ſpreading panicle of Oats and many other graſſes, and of London Pride *Saxifraga umbroſa*, as well as of various other flowers. It is alſo uſed to characterize the ſtems of various plants which ſpread in a lax indeterminate manner on the ground; for inſtance the Common Chickweed or *Stellaria media*, Sm. Fl. Brit. and the no leſs common *Veronica Chamædrys*, and *agreſtis*, ſuch ſtems being generally procumbent at their origin, and aſcending towards the extremity.

DIFFUSION, from *diffundo*, I pour out, I dilate, the act whereby a body is ſpread, or ſtretched out, ſo as to take up more ſpace.

The ſchoolmen make three kinds of diffuſion: the firſt, that whereby a pure quality is diffuſed; as cold, force, &c. This they diſtinguiſh into equal, whereby equal portions, or degrees, of the quality are diſtributed upon equal parts of the medium; thus, when a direct motion is impreſſed on a moveable, all the parts of the moveable receive an equal impetus; and unequal, when unequal degrees of the quality are diſtributed on different parts of the ſubject; thus it is, that force is impreſſed on a lever, and cold propagated through a medium.

The ſecond kind of diffuſion is that performed by the motion of bodies: ſuch is the diffuſion of light, ſound, ſmell, magnetic, electric virtues, &c.

The third is performed partly by the motion of corpuſcles, and partly by the diffuſion of a quality; and thus they hold fire to be diffuſed.

But the modern philoſophers reject the notion of qualities, and their diffuſion. According to them, there is no other diffuſion, but that of corporeal ſubſtance, emitted in minute effluvia, or particles, into a kind of atmoſphere all around the body; which diffuſion of corpuſcles ſome call atmoſpherical, as being ſuppoſed to be terminated by a circle, whereof the diffuſing body is the centre. Every body, it is now proved, has its ſphere of activity, or diffuſion, within which the particles, or corpuſcles, torn from it, and flying away, have a ſenſible effect; as we ſee in odorous, ſonorous, &c. bodies. See QUALITY; where the phyſical law of the diffuſion of qualities is laid down.

DIG, in *Agriculture*, a term which is ſometimes provincially applied to a mattock, and which likewiſe ſignifies the breaking up the ground by a ſpade or other ſimilar tool.

DIG, in *Geography*, a town of Hindooſtan, in the country of Mowat; 63 miles ſouth of Delhi.

DIGAMMA. See F.

DIGAMY, the ſame with bigamy. See BIGAMY.

DIGASTRICUS, in *Anatomy*, one of the muſcles of the lower jaw, called alſo by the name of biventer maxillæ inferioris. It is deſcribed in the article DEGLUTITION.

DIGBA, in *Ancient Geography*, a town of Aſia, ſituated on the bank of the Tigris. Pliny places it in Babylonia, and Ptolemy in Meſopotamia.

DIGBY, *Sir* KENELM, in *Biography*, was the ſon of ſir Everard Digby, who was executed for the ſhare which he had in the gunpowder-plot. Kenelm was but three years old when he loſt his father. Great care was taken to initiate him in the Proteſtant religion, and at a proper age he was ſent to Oxford to complete his ſtudies. He then made the tour of Europe, and on his return was preſented to the king, who not only gave him a gracious reception, but conferred on him the honour of knighthood. This was in 1623. He afterwards appeared with ſplendour at the court of Charles I., by whom he was greatly eſteemed. This prince made him gentleman of his bed-chamber, firſt commiſſioner of the navy, and a governor of the Trinity-houſe. He likewiſe granted him letters of repriſal againſt the Venetians, and with a ſmall fleet fitted out at his own expence, he obtained ſome brilliant ſucceſſes. He had long been regarded as a prodigy of learning, and he now returned to his native country with a high reputation for true valour and enterprize. Upon a viſit to France ſir Kenelm, warmly aſſailed by ſome eccleſiaſtics, was reclaimed to the religion of his fathers, and in 1636 reconciled himſelf to the church of Rome. He ſoon diſplayed the zeal of a new convert, by publicly defending the faith he had adopted, in two diſtinct works. On the commencement of the troubles with Scotland, ſir Kenelm was inſtigated by the queen to write to the Catholics of England, to obtain from them a voluntary contribution, in ſupport of the expedition againſt the Scots: for this he was afterwards impriſoned by the parliament; but during his confinement, which was probably not very rigorous he occupied himſelf with philoſophical ſpeculations. He wrote obſervations on the "Religio Medici" of ſir Thomas Browne, which have been highly eſteemed, as well on account of the politeneſs of the language, as the acuteneſs with which he confutes ſome of the notions of the author. He exhibited alſo a good taſte for allegorical interpretations, by an elaborate commentary on a ſtanza in the ninth canto of the ſecond book of the Fairy Queen, in which Spencer has introduced ſome of the myſteries relative to numbers. He was at length liberated, and went to France, where he was well received; and at this period he became acquainted with Des Cartes. Theſe philoſophers had many long and learned converſations on the nature of the ſoul, and on other intereſting topics, upon ſome of which they could not agree; but they parted full of mutual eſteem for each other. At Paris he publiſhed, in 1644, his own philoſophical ſyſtem, in two parts, entitled "A Treatiſe of the Nature of Bodies," and "A Treatiſe declaring the Operations and Nature of Man's Soul, out of which the Immortality of reaſonable Souls is evinced." When the cauſe of Charles was hopeleſs, ſir Kenelm came over to England, to make compoſition for his eſtate, but he was not permitted to remain in England, and parliament denounced againſt him the penalty of death, ſhould he return again without permiſſion. This was granted him by Cromwell in 1655, when he continued engaged in his own affairs the greater part of the year, and it is believed that he was likewiſe employed in conciliating the Catholic party to the protector's adminiſtration, upon the condition of a free toleration, a meaſure to which Cromwell was by no means averſe. Sir Kenelm reſided in the ſouth of France in 1656 and 1657, frequenting the ſociety of the learned and ingenious, before whom he was fond of making a parade of his philoſophical knowledge. He afterwards reſided in Germany for two years; but on the reſtoration he came again to his native country, where he met with a polite reception at court, but was not brought forward into active life. Henceforward he ſpent his time in a learned retreat, frequenting the meetings of the Royal Society, of which he was a member, and receiving the viſits of men of ſcience, at his own houſe in Covent Garden. He ſuffered very much from repeated attacks of the ſtone, which, in 1665, put an end to his life, at the age of ſixty-two. In early life lord Clarendon deſcribed ſir Kenelm as a man of a very extraordinary perſon and preſence, which drew the eyes of all men upon him, which were more fixed by a wonderful graceful behaviour,

like thoſe of comfrey. *Flowers* yellow; on branched peduncles. Sent by Dr. Houſton to Miller from La Vera Cruz. 5. C. *folioloſa*. Willd. 3. "Leaves oblong, nearly entire, half embracing the ſtem, downy; peduncles one-flowered, finally much elongated." *Stem* much branched, diffuſe, downy; branches thick ſet with leaves. *Leaves* alternate, downy on both ſurfaces. A native of the Eaſt Indies. 6. C. *patula*. Mart. 30. Willd. 4. Hort. Kew. 3. 184. "Leaves elliptical, ſerrated, villous underneath; calyxes ſomewhat globular; ſcales lanceolate, awl-ſhaped; branches ſpreading." *Root* annual. *Stem* a foot and half high, taper, ſlightly covered with a mealy down. *Leaves* about four inches long, and two broad in the middle, diminiſhing gradually in ſize on the upper part of the ſtem and branches. *Flowers* purple; peduncles at the end of the branches generally three-flowered; calyxes ſoft and ſwollen in the middle; ſcales ſmall and acute. A native of the northern parts of China, producing a ſucceſſion of flowers from July to the end of autumn. 7. C. *paniculata*. Willd. 5. "Leaves oblong, ſeſſile, downy on both ſurfaces; lower ones petioled; toothed; teeth reflexed; ſtem panicled; corymbs pedunculed, axillary." *Stem* four feet high, about the thickneſs of a ſwan's quill, erect, cylindrical, hollow, ſtriated; branches alternate, erect, ſimple. *Leaves* on the ſtem petioled, on the branches ſeſſile. *Calyx-ſcales* linear-awl-ſhaped, ſpreading, reflexed. A native of the Eaſt Indies. 8. C. *bifrons*. Linn. Sp. Pl. 7. Mart. 9. Willd. 6. (Eupatoria conyzoides maxima canadenſis; Pluk. alm. 141. tab. 87. fig. 4.) "Leaves ovate-oblong, embracing the ſtem, ſerrated, wrinkled." *Root* thick, fibrous. *Stems* ſeveral, erect. *Leaves* rough. *Flowers* yellow, in round terminal bunches. A native of Canada, flowering in July. Diſtinct from Inula bifrons. 9. C. *bifoliata*. Linn. Sp. Pl. 9. Mart. 10. Willd. 7. (Eupatoria conyzoides integro jacobææ folio; Pluk. alm. 140. tab. 177. fig. 1. C. axillaris; Lam.?) "Leaves oval, toothed; peduncles two-leaved; bractes oppoſite;" Linn. "Leaves cuſpidate-toothed; lower ones petioled, roundiſh egg-ſhaped; upper ones ſeſſile, oblong, wedge-ſhaped at the baſe; racemes axillary, leafy at the baſe, peduncled;" Willd. "Leaves inverſely egg-ſhaped, unequally and finely toothed, petioled; racemes axillary, leafy at the baſe, forming a terminal panicle;" Lam. *Stem* a foot and half or two feet high, ſimple, ſlightly ſtriated, downy. *Leaves* alternate, ſoft, green, and almoſt ſmooth above, cinereous and downy underneath. *Flowers* ſmall; bractes truly alternate, though ſome ſeem oppoſite; calyxes villous, reddiſh; Lam. Deſcribed from a dried ſpecimen in the Herbarium of Commerſon. In ſmaller ſpecimens, probably the growth of a poor ſoil, the peduncles are one-flowered, with oppoſite bractes. In larger ſpecimens the racemes are from three to ſix-flowered; peduncled, furniſhed with two, either oppoſite or alternate bractes, and ſometimes with four alternate ones; bractes oblong, ſeſſile, generally entire; Willd. A native of the Eaſt Indies and the Iſle of France. 12. C. *pubigera*. Linn. Mant. 113. Mart. 11. Lam. 9. Willd. 8. Lour. Cochinchin. 495. (Sonchus volubilis; Rumph. Amb. 5. 299. tab. 103. fig. 2,) "Leaves oblong, ſomewhat toothed, nearly ſeſſile; peduncles woolly, about two-flowered." *Branches* with a few ſcattered hairs. *Leaves* alternate, wedge-ſhaped at the baſe, green on both ſurfaces, with a few ſcattered hairs, not ſcabrous; Linn. *Stem* ſomewhat ſhrubby, eight feet high, cylindrical, climbing, branched. *Leaves* broad-lanceolate, ſomewhat pubeſcent, ſcattered, petioled. All the florets immerſed in a ſimple down; Lour. A native of the Eaſt Indies and China. 11. C. *ſtricta*. Willd. 13. "Leaves linear-lanceolate, attenuated at the baſe, quite entire, hairy; flowers in corymbs; ſtem panicled, ſtiff." *Root* annual. *Stem* a foot and half high, erect; branches ſhort, erect, cloſe to the ſtem. *Leaves* alternate, numerous, an inch long, obtuſe, with a point, narrowed at the baſe. *Corymbs* ſmall, faſtigiate at the tops of the branches. *Flowers* ſmall; down reddiſh. A native of the Eaſt Indies. 14. C. *caneſcens*. Linn. jun. Sup. 367. Mart. 5. Willd. 18. Thunb. prod. 153. (C. pinifolia; Lam. 18. Elichryſum peregrinum anguſtifolium floſculis ſpadiceis in apices crinitos deſinentibus; Seb. Muſ. 1. 38.) "Leaves linear, ſtiff, folded back at the edges; downy underneath; panicle faſtigiate." Whole plant hoary. *Stem* from twelve to fifteen inches high, nearly ſimple, cylindrical, ſtiff, lateral branches ſhort. *Leaves* three inches long, a line broad. *Flowers* purple; calyx ſhort; ſcales imbricated, lanceolate, villous, only half the length of the flowers; down intermixed with the florets; giving the flowers a feathered appearance. 15. C. *oleæfolia*. Lam. 20. Willd. 15. (C. orientalis pumila incana oleæfolio; Tourn. cor. 33.) "Leaves lanceolate, attenuated at the baſe, obtuſe, downy; corymb terminal; ſtem ſimple." *Root* perennial. *Stem* ſeven or eight inches high, erect. *Leaves* not an inch long, three or four lines broad, ſcattered. *Flowers* in a cloſe faſtigiate corymb; peduncles ſcaly; calyx oblong; ſcales cloſely imbricated, egg-ſhaped, obtuſe; down reddiſh, longer than the calyx. A native of America. 16. C. *viſcoſa*. Mart. 34. Houſt. MSS. "Leaves egg-ſhaped, ſerrated, villous; flowers axillary and terminal." *Root* annual. Whole herb viſcid. *Stem* a foot high, branched. *Leaves* one at each joint, ſeſſile. *Flowers* white; peduncles ſlender; generally three-flowered. *Seeds* chaffy. A native of La Vera Cruz. 17. C. *mollis*. Willd. 19. "Leaves rhomboid-egg-ſhaped, nearly ſeſſile, toothed, pubeſcent, tomentous underneath; ſtem naked upwards; flowers in a corymb." *Branches* cylindrical, ſtriated. *Leaves* an inch long, very white underneath. *Corymb* terminal; branches alternate, few-flowered, divaricated; peduncles one-flowered; calyx-ſcales linear-lanceolate; down long, ſnow-white. 18. C. *chenopodifolia*. Lam. 12. Willd 20. "Leaves ovate-deltoid, unequally ſerrated, ſoft; racemes ſhort, terminating the ſtem and branches." *Stem* tomentous upwards. *Leaves* alternate, petioled, tomentous when young, afterwards nearly ſmooth. *Flowers* whitiſh, ſeſſile, four or five together at the top of the ſtem and branches; calyx-leaves linear, very narrow, tomentous, almoſt equal; bractes cloathed with fine ſilky decumbent hairs. A native of the Iſle of Bourbon. There is a variety with broader, roundiſh-egg-ſhaped leaves, a little cut at the baſe. 19. C. *cinerea*. Linn. Sp. Pl. 14. Mart. 16. Lam. 3. Willd. 21. (Senecio indica, foliis ternis crenatis; Burm. Zeyl. 211. tab. 96. fig. 1. S. indicus atriplicis folio; Mor. Hiſt. 106. tab. 17. fig. 7. Olus ſcrophinum; Rumph. 6. tab. 14. fig. 1.) "Leaves egg-ſhaped, ſlightly crenate; lower ones obtuſe, upper ones acute; panicles naked, terminal;" Lam. *Root* annual. *Stem* about a foot high, ſlender, pubeſcent. *Leaves* ſmall, rather diſtant, narrowed into a petiole, cinereous-green, whitiſh underneath. *Flowers* purple, ſmall; peduncles branched, almoſt capillary; calyx-ſcales acute; down white, longer than the calyx. A native of the Eaſt Indies. 20. C. *prolifera*. Lam. 7. Willd. 22. (Sonchus volubilis Javanus; Rumph. 5. 299. tab. 104. 1?) "Branches proliferous at the top; leaves egg-ſhaped, toothed-angular, narrowed into a petiole; corymbs cloſe, terminal." *Branches* finely ſtriated, full of pith, ſcabrous, producing near the top ſome ſmaller villous branches, and giving the plant a proliferous appearance. *Leaves* ſmall, acute, green, and almoſt ſmooth above, hoary, and cloathed with ſhort hairs underneath. *Corymb* almoſt ſeſſile; calyx-ſcales awl-ſhaped, down white, the length of the calyx. A native of the iſland of Java. 21. C. *heterophylla*. Lam. 8. "Some of the leaves a little heart-ſhaped; others

large, and often complicated ſtomach: while the carnivorous tribes have a ſhort and ſmall digeſtive canal, conſtructed in ſuch a manner as to afford a rapid paſſage to their animal food, which contains more nouriſhment under a ſmaller bulk, which is digeſted more eaſily and readily, and might have putrefied if detained too long. In this point of view, man holds a middle rank between thoſe ſpecies which eat vegetable food, and thoſe which ſubſiſt on fleſh; he is adapted for both theſe kinds of nouriſhment, and is not excluſively herbivorous or carnivorous, but, by the very nature of his frame, *omnivorous*. This queſtion, which is ſo eaſy of ſolution, has often occupied the attention of the phyſician, naturaliſt, and philoſopher, who have derived tolerably plauſible arguments on both ſides, from the form and number of the teeth, ſtructure of the inteſtines, &c. We have already ſhewn, in the deſcription of the teeth under the article CRANIUM, that their form, &c. would lead to the ſame concluſion, as we have now pointed out.

Hunger and Thirſt.

The want of food ariſes from the neceſſity of obviating the loſſes which our body is conſtantly ſuffering, in the performance of its various functions; and of preventing, by the reparation of theſe loſſes, the fatal effects which they would otherwiſe occaſion. It is announced in all animals by an active and imperious feeling, which we call hunger, when it regards ſolid food; thirſt, when its object is liquids. Animal life could not be continued to the term allotted by the Creator without a conſtant ſupply of nutriment; we are incited to take this by the pleaſure attendant on the gratification of our natural wants; which pleaſure is always increaſed in proportion to the neceſſity of gratifying them. The appetite of the luxurious glutton can hardly be rouſed by the ſpices of either India; while the ploughman or hunter, returning from his daily labour, finds a reliſh in the coarſeſt bread, and ſimpleſt drink, that might be envied by the pampered palate of the epicure. But man and animals, who ſeem naturally prone to inactivity, and averſe from labour, are not governed, in this reſpect, by pleaſure alone: they are rouſed by the loud and repeated admonitions of an urgent, terrible, and, at laſt, intolerably painful ſenſation, to exert themſelves and labour for the acquiſition of food and drink.

Theſe wants are more urgent in the early periods of life, when, beſides the reparation of daily loſſes, materials of growth muſt alſo be ſupplied. Hence, the nutritive phenomena, and, conſequently, the digeſtive functions, are more active, as long as the body continues growing. The admonitions of hunger are alſo more preſſing in robuſt individuals who are engaged in laborious exertions, eſpecially in the open air, and who, conſequently, experience a greater daily loſs. Labouring men, like children, take daily four meals, or more, and thoſe plentiful ones. Fatigue diſſipates in the former what is applied to purpoſes of growth in the latter.

Habit conſiderably modifies our feelings in regard to food. The periodical returns of hunger at the arbitrarily fixed periods of our meals; and the loſs of appetite experienced when the accuſtomed time has gone by without our having taken a meal, ſtrongly illuſtrate this. Hence ſome have drawn a diſtinction between hunger and appetite, conſidering the former as the natural expreſſion of a real want; the latter as the habitual reſult of an artificial deſire. The laſt is conſiderably influenced by the imagination and the will. The recollection of a diſguſting object will often diſſipate the appetite, and even change it into an averſion from food: profound meditation, agreeable amuſements, or ſtrong paſſions, deaden our ſenſe of hunger, and render us for a time inſenſible to its effects.

A want of food produces a diminution in the weight of the body, which is already very ſenſible at the expiration of twenty-four hours; emaciation from the general abſorption of the adipous ſubſtance; coldneſs; proſtration of ſtrength; and the moſt painful dragging ſenſation at the pit of the ſtomach. It has alſo been aſſerted that the blood and other fluids degenerate, become alkaline, acrid, and even putrid; that the blood-veſſels and nerves are eroded, and hence that hemorrhages enſue, &c. But we believe that theſe circumſtances are not drawn from obſervation, and that no ſuch changes enſue.

A healthy adult certainly could not abſtain from food for twenty-four hours without feeling very conſiderable weakneſs; and, if the abſtinence were continued for eight days, death would be the highly probable event. Indeed in many inſtances a ſhorter period has ſufficed. Generally ſpeaking, the fatal event approaches more rapidly in proportion to the youth and ſtrength of the ſubject. Thus count Ugolino, (whoſe dreadful fate has been immortalized by Dante) condemned to periſh by hunger, and ſhut up with his children in a dungeon, died the laſt on the eighth day, after ſeeing his four ſons periſh ſucceſſively amid the convulſions of rage and the cries of deſpair, victims of the moſt horrible vengeance recorded in the annals of human crimes.

Yet numerous inſtances have occurred, in which, contrary to the accuſtomed courſe, abſtinence has been ſuſtained for much longer periods; for weeks, months, and even, if the narratives may be credited, years. Haller has collected a long liſt of ſuch examples, (Elem. Phyſiol. lib. 19, ſect. 2.) and if all of them ſhould not be authentic, there is yet a ſufficient number of well atteſted facts to ſhew, that perſons, under certain circumſtances, can diſpenſe with food for a long time. In Duncan's Annals, vol. 4. is the account of a woman who ſurvived after being buried in ſnow for eight days; the ſenſation of hunger ceaſed after the firſt day. Thirſt was the predominant feeling, and it was alleviated by ſucking the ſurrounding ſnow. In the 5th vol. of the ſame work, is the account of a lunatic who would often abſtain from all food both ſolid and liquid for fourteen days without appearing to be much weakened by it. In the medical communications, Dr. Willan has mentioned a young man, who, having taken up ſome ſtrange religious notions, lived for ſixty days on a pint of water ſlightly flavoured with orange juice each day. Dr. Birch, in his Hiſtory of the Royal Society, vol. ii. ſpeaks of Johanna Naunton, a young lady of noble extraction, reduced to indigence, who abſtained from food to conceal her poverty, and ſupported herſelf on lemon juice for 78 days. Haller mentions an inſtance of one, and another of three years abſtinence, as particularly authentic and well aſcertained. Elem. Phyſiol. tom. vi. p. 171.

In explanation of theſe facts, we may obſerve, that moſt of the ſubjects were weak and delicate women, living in a ſtate of complete inaction; many of them almoſt inſenſible, ſtupid, and lethargic. The men in every inſtance were melancholic. In ſuch ſubjects, the organs were not ſenſible to the natural ſtimuli, and the cuſtomary loſſes of the body in perſpiration, ſweat, &c. were not obſerved: the exiſtence of life almoſt extinct was only proved by a pulſe hardly to be felt, and a reſpiration ſcarcely perceptible performed at long intervals. Such individuals may be compared to hybernating animals; where the pulſe and reſpiration are equally obſcure, where no food is taken, and conſequently no fœces are voided, &c. In many inſtances of abſtinence, water was freely taken, which would undoubtedly obviate many of the ills ariſing from hunger.

The

The ſymptoms of hunger are, firſt an unpleaſant ſenſation, and then a very peculiar dragging and lacerating pain in the ſtomach; increaſed ſenſibility, want of ſleep; debility, yawning and fainting. The pain remits but returns with increaſed violence; the mind becomes affected, and delirium or mania cloſes the ſcene. So dreadfully painful are the ſenſations experienced from a privation of food, that they overcome the moſt violent antipathies, and the deareſt affections. Bones, putrid meats, hides of animals, leather, in ſhort the moſt diſguſting ſubſtances, are greedily devoured. The rage of the ſufferer has ſometimes attacked his own ſpecies, his friends, his children, and even the ſubſtance of his own body. The ſtomach, during abſtinence, becomes very much contracted; and hence we can underſtand, how a very ſudden diſtention of the organ, in this ſtate, ſhould cauſe pain, fainting, illneſs, or even death. Hence the neceſſity of allowing a very ſmall quantity of food to perſons in this condition; and of proportioning our ſupplies not to what the appetite demands, but to what the ſtomach will bear.

A caſe is recorded in Dr. Currie's Reports, of a patient who died of inanition from ſtricture of the œſophagus; of which we juſt mention the heads, conſidering it valuable from the rareneſs of ſuch records, and the philoſophic accuracy of the obſerver. From the 17th of Oct. to Dec. 6, he was ſupported without the aid of the ſtomach, by means of broth clyſters, and was immerſed in a bath of milk and water; theſe circumſtances, would, no doubt, modify the ſymptoms. He had at one time a parched mouth; a bliſter diſcharged only a thick coagulable lymph; and the urine was ſcanty, extremely high coloured, and intolerably pungent. This want of aqueous parts in the fluids, is, no doubt, the circumſtance, which has given riſe to the notion of their acrimony. The heat was natural and nearly uniform from firſt to laſt; the pulſe was perfectly natural until the laſt days. His ſleep was ſound and refreſhing; his ſpirits even, and his intellect perfect until the four laſt days, when the clyſters were no longer retained. Viſion was deranged on the firſt of December, and delirium followed on the next day; yet the retina was unuſually ſenſible, and the ſenſe of touch remarkably acute. The ſurface and extremities were ſometimes of a burning heat, ſometimes clammy and cold. On the fourth the pulſe became feeble and irregular, and reſpiration laborious; and in ninety-ſix hours after all means of nutrition, as well as all medicine had been abandoned, he ceaſed to breathe. He was never much troubled by hunger; thirſt was at firſt troubleſome, but relieved by the tepid bath. Currie's Reports, vol. i.

Many circumſtances have been adduced to explain the proximate cauſe of hunger; *viz.* the friction of the coats of the empty ſtomach againſt each other; the irritation produced on its ſurface by the action of the accumulated gaſtric juice; the contraction of its muſcular fibres; the compreſſion and folding of the nerves from this contraction; and the dragging of the liver and ſpleen on the diaphragm, when they are no longer ſupported by the ſtomach and inteſtines on account of their empty ſtate. It would be a waſte of time to comment on the inſufficiency of theſe explanations. A more rational illuſtration conſiders hunger as a ſenſation, excited in the ſtomach by ſympathy with the wants of the conſtitution at large. For if any circumſtance impedes the nutrition of the body, hunger ſtill remains, although the ſtomach be diſtended. This happens in ſchirrous pylorus, where the nutritive maſs cannot paſs into the ſmall inteſtine, to be ſubjected to the action of the lacteals, where the loſſes of the body cannot therefore be repaired. In diſeaſed meſenteric glands the ſame phenomenon is noticed; *viz.* voracious hunger in ſpite of the quantity of food taken. In both theſe inſtances, we ſee how ineffectual all the above mentioned cauſes would be in explaining the ſeat of hunger; and again, in the caſe quoted from Dr. Currie, hunger was not felt, although the ſtomach continued empty for ſo long a time. That hunger is a nervous ſenſation of the ſtomach ſeems probable, from its being influenced, like all the phenomena dependent on nervous action, by habit, and by mental cauſes; from its being increaſed and excited by cauſes which act on the ſenſibility of the organ, as by ſpirituous drinks and ſpices, even when the ſtomach is filled; and by its being diminiſhed by means of the contrary kind, as we know that opium will act in deadening the acute feelings of hunger, and that the Turkiſh and Indian fanatics, called Mollahs and Faquirs, are enabled, by this means, to ſupport their long faſts.

Thirſt is a feeling of a ſtill more urgent kind, and requiring inſtant ſatisfaction ſtill more imperiouſly than hunger; particularly when it is felt in a hot climate. Its effects are depicted in the account of the horrible ſufferings experienced by our countrymen in the black hole at Calcutta, when, however, the great mortality may not be aſcribable to thirſt alone. According to the relation of Plutarch, Lyſimachus, one of the braveſt ſucceſſors of Alexander, was compelled to ſurrender with his army, from the want of water; and Paul Jovius relates that the emperor Charles V. loſt ſeveral men in his African expedition from the ſame cauſe. Thirſt becomes very urgent when any of the watery ſecretions are augmented, as in dropſy and diabetes; and it is one of the moſt diſtreſſing ſymptoms in fevers, and inflammatory complaints, particularly inflammation of the ſtomach. Hot ſpices, ſaline ſubſtances, and particularly common ſalt, encreaſe it, as do all cauſes augmenting the different ſecretions. Hence it ſhould ſeem that the end of drinking, is to repair the loſſes of our fluids.

The ſeat of thirſt is in the mouth and fauces; which parts are not lubricated by the uſual ſecretion, and conſequently become dry. If it be not ſatisfied, a general irritation comes on, the ſenſation of dryneſs increaſes, and is accompanied with a burning feel, and an acute fever enſues. Theſe ſymptoms do not ceaſe until a ſupply of fluid, conveyed into the ſtomach, reſtores the ſecretions of the mouth and throat. Yet, although thirſt at firſt appears ſo urgent, drink is by no means ſo neceſſary to the continuation of life, as food. Several ſpecies of warm-blooded animals, as mice, quails, parrots, &c. can ſubſiſt without drinking; and individuals of our own ſpecies have, in ſome inſtances, by perſeverance, conquered the ſenſation of thirſt. Sir G. Baker has recorded a moſt memorable example in the Tranſactions of the College of Phyſicians, of a man who lived in perfect health for many years without drinking.

Food. Every thing that can afford nouriſhment to an animal body muſt have previouſly poſſeſſed life, and conſequently all food is derived from either the animal or vegetable kingdom. Minerals ſerve for ſeaſoning and medicine; and ſome miſerable ſavages have appeaſed the feeling of hunger by taking a greaſy kind of earth into the ſtomach. Some of the lower animals, as the earth-worm, alſo ſwallow earth; but they may extract vegetable and animal remains from this without deriving nouriſhment from the earth itſelf.

Any thing which is analagous to the nature of the body to be nouriſhed, and is ſuſceptible of being changed into its ſubſtance, may conſtitute an article of food. The eſſential characters of alimentary ſubſtances are, that they will eaſily change their nature and properties; that they yield readily to the means of decompoſition applied to them; diſſolve eaſily in water; and are ſubject to that ſpontaneous motion which conſtitutes fermentation. The ſubſtances which unite

theſe properties muſt alſo be of a compound nature, that is, muſt conſiſt of ſeveral elements, otherwiſe they would be incapable of the neceſſary decompoſition: they muſt alſo have already experienced ſome alteration; and hence the utility of the preliminary action of the organs of maſtication and inſalivation.

The food of man takes in almoſt every variety of both animal and vegetable ſubſtances. It conſiſts therefore of ſeveral unchangeable principles, foreign to the buſineſs of nutrition, combined with others in which the nutritive power reſides. The latter varies in its characters and proportions. Mucilage, gelatine, gluten, albumen, fecula, fibrine, ſugar, and the baſe of oxalic acid, are the general modifications under which the nutritive ſubſtance preſents itſelf. Each of theſe varies according to the nature of the heterogeneous principles with which it is aſſociated.

In the numerous plants which do actually, or which might ſerve for food, mucilage ſometimes exiſts alone, or mingled with extractive, colouring, acrid, bitter or odorous matters; or diluted with various proportions of water. It is often united with oxalic acid and ſugar; ſometimes with a very active volatile principle of a very acrid taſte and penetrating odour. Laſtly, it furniſhes the matter of gums and vegetable jellies; in one of which the nutritive principle is imperfectly formed, while in the other it is brought into a very ſmall volume.

Gum tragacanth, ſeneca, cherry-gum, &c. are examples of this matter. It is no where cultivated, nor even collected for food; ſo that we might be apt to conſider it as incapable of affording any nouriſhment, if it were not known that the caravans croſſing the ſandy deſerts of Africa, over which they have brought gum ſeneca, have in many inſtances loſt their way, exhauſted their proviſions, and been obliged to live on this gum for many weeks, having nothing elſe but water alone, and a very ſparing ſupply of that. Mucilage is alſo contained in moſt vegetable juices, and in the ſtems and other parts of plants.

In the fleſh of animals which we uſe for food, the gelatine is united with fibrous, extractive, ſaline, and earthy particles. It is mingled with fat, and with ſerous or lymphatic fluids. It is found in various degrees of tenacity and conſiſtence; in which it determines all the ſenſible differences of the white organs, which contain an abundance of gelatine. In a word, it forms the animal jellies, which conſtitute a mild, light, and wholeſome food.

Vegetable gluten is always found combined with other ſubſtances ſoluble in water, without which it could not be diſſolved in, and blended with, our juices. It abounds in the gramina, where it is united with fecula, extractive principle, colouring matter, mucilage, and an earthy ſubſtance.

The albumen of animal matters reſembles, in many points, the vegetable gluten. The whole white, and a great part of the yolk of an egg, are a compoſition of albumen, and colouring, and oily principles. The caſeous matter of milk is a modification of albumen; which, together with the principles of butter and ſugar, compoſes that ſoft emulſive liquor, ſo favourable to the conſtitution of infancy. The moſt nutritive plants are thoſe whoſe baſe and prevailing principle is the amylaceous fecula. It exiſts ſometimes completely pure, and free from extraneous admixture; ſometimes united with mucilage, oils, or gluten; ſometimes with ſugar, extractive, or colouring matters; ſometimes with earthy, acid, or ſaline principles; and very rarely with noxious, or poiſonous matters. Wheat is compoſed of gelatinous matter and fecula. Theſe two principles, acted on by the fermentative proceſs, form bread, the nutritive qualities of which are not ſurpaſſed by any ſubſtance. It is ſo much the more proper for animalization, inaſmuch as the fermentation has already brought it into a ſtate fit for decompoſition.

The principle now alluded to, which conſtitutes the farinaceous matter of vegetables, is contained, perhaps, in the largeſt proportion in rice; and wheat is the next to this. Other grains are only ſubſtitutes for theſe; except maize, which is eaſily cultivated, and contains much farinaceous matter. The legumina contain much of the ſame principle; as alſo nuts, and the ſeeds of the cucurbitaceæ and poppy, although not uſed for food. It exiſts, probably, in the ſtems of ſome plants, as the palmæ, from the expreſſed juice of which ſago is formed; in the roots of many claſſes, as the potatoe, yam, and pignut, in which it is very abundant.

The fibrine of the muſcles and blood partakes of the properties of gluten and fecula: it admits of a very ſpeedy aſſimilation, and exerts a more marked, rapid and extenſive influence on the ſtrength in general than any other food; yet it reſiſts the digeſtive powers, when, deprived of gelatine or dried, it is reduced to a hard coriaceous ſubſtance. It forms a cloſe and firm, but delicate and diviſible texture, in the muſcles of healthy animals, which form a light and ſucculent kind of food. An extractive colouring matter generally adheres to the fibrous ſubſtance; and the differences in its quantity or quality influence the appearance and nutritive powers of our various animal foods.

Sugar, and the oxalic baſe, which can hardly be ſeparated from it, are produced by both kingdoms. The vegetable acids are convertible into a ſugary ſubſtance, which beſtows on them whatever nutritive powers they may poſſeſs. Other acids, beſide the oxalic, are unfit for nouriſhment; and they only acquire that property by an admixture of the latter or of ſugar or mucilage. The ſame principles exiſt in various proportions in the fruits employed for food. The reſpective quantities of mucilage, ſugar, acid, and water, indicate how far they are ſuſceptible of digeſtion, and, conſequently, nouriſhing.

Sugar exiſts in moſt vegetables, but is moſt abundant in the ſugar-cane, from which alone it is furniſhed to any great amount, in the ſugar-maple and the beet-root. Excepting what is ſupplied from the vegetables above-mentioned, and which hardly forms the food of any perſon, its ſources for the purpoſes of food are not very general, being confined principally to dates, grapes, figs, and ſome other fruits. Fruits indeed, in general, contain ſugar; many of them in ſufficient quantity to afford conſiderable nouriſhment. But the three ſpecies juſt enumerated are thoſe on which many individuals live almoſt entirely; the ſugar being nearly their only nouriſhment: this obſervation holds with regard to dates in ſome of the African tribes, grapes in ſome parts of Portugal and Spain, and figs in Greece and the Grecian iſlands.

Expreſſed oils, found in vegetables, are alſo capable of being digeſted; the ſeeds containing them, and eſpecially nuts, are in many inſtances the principal food of the inhabitants of a country, as cocoa-nuts in America and the Eaſt. Theſe ſeeds indeed contain farinaceous matter, but in too ſmall proportion to afford nouriſhment of itſelf. The oily animal fluids alſo afford nouriſhment; the moſt common ſource of theſe is the fat of meat and butter, but there are perſons who drink with avidity ſpermaceti and train oil.

The ſmall number of principles juſt enumerated, as aſcertained by the reſearches of modern chemiſtry, fix the particular characters on which the natural diſtinctions of our aliments muſt reſt. The numerous modifications which theſe muſt undergo, from a variety of cauſes, will influence our choice of particular ſpecies of food; but theſe conſiderations,

as well as thoſe which regard the quantity and proportions both of ſolid and liquid food, belong to the ſubject of diætetics. See DIET.

The food of man, in the firſt ages, ſeems to have been drawn from the vegetable kingdom; in thoſe times, milk, derived firſt from the breaſt of the female, and afterwards from flocks and herds, was the ſole nourihment furniſhed by animals. Soon, however, fleſh was added to the food, and the juice of the grape to the drink of the human ſpecies. Subſequently the earth, air, and water, have been exhauſted to adminiſter to the wants or luxury of mankind; and ſubſiſtence has been drawn indifferently from animal or vegetable ſubſtances.

The power of adopting all kinds of diet would naturally lead us to expect the differences which we actually find in this reſpect among the numerous nations ſcattered over the face of the earth. In the moſt remote antiquity we read of tribes in Africa, and of the Indian prieſts and philoſophers, who lived only on vegetables; while the Ethiopians, Scythians, and Arabians, ate nothing but fleſh or animal food. Some tribes on the ſea-coaſt ſubſiſted entirely on fiſh. Modern hiſtory diſcovers the ſame difference of regimen. A vegetable diet ſeems ſuitable to the burning countries under the equator, and we, accordingly, find nations there who have completely adopted it, and who abſtain ſo much the more ſeverely from all animal foods, inaſmuch as it is an article of their religious faith. It is alſo rigorouſly obſerved in ſome more temperate climates. Potatoes, cheſnuts, maize, and the legumina, ſatisfy the wants of the Alpine peaſant; and numerous inſtances might be quoted of individuals and tribes whoſe ſole food has been vegetables and water. The frozen regions of the north demand a different diet; and the animal kingdom ſupplies the food of man near the pole. In the north of Europe, where the cold is leſs rigorous, the Swede, Dane, Ruſſian, German, and Engliſhman, eat much meat and little vegetables. The Tartars in Aſia, and entire tribes of ſavages in North America, live on raw and half putrid meat. The herbivorous animals afford the beſt animal food; but the Tartars, Samoieds, Eſquimaux, and others, do not refuſe food derived from other claſſes.

The muſcles of the herbivora are moderately ſoft and contain much gelatine; their milk is mild, the urine and fœces not very fœtid. Beſides the cow and ſheep, which are almoſt our only ſupply, the horſe, aſs, camel, and goat, are uſed in other regions. The fleſh of the carnivora is harder, and peculiarly ſtrong and fœtid. Yet dogs were eaten in the time of Hippocrates, and ſtill by ſeveral ſavage tribes; and the ſeal and walrus have often yielded a ſupply to the ſailor. All the granivorous, herbivorous, and inſectivorous birds, are eaten; the carnivorous very rarely; and the piſcivorous never, except in the laſt neceſſity, on account of their diſguſting ſmell and taſte. Fiſhes ſupply an abundant ſource of aliment, and even reptiles and inſects are employed in ſome inſtances.

The miſerable inhabitants of New Holland lived wholly on fiſh when that country was firſt diſcovered; and the ſame circumſtance may be affirmed of various tribes on the ſhores of Arabia and the Perſian gulph. In the iſlands towards the North of Scotland a great part of the food ariſes from the ſame ſource; ſtill more in the Ferro iſlands, in Iceland, and Lapland; and the whole in Greenland, and in the neighbourhood of the mouths of the large ſtreams in the north of Aſia. This claſs has alſo ſupplied ſome very ſingular kinds of aliment: the roes of the ſturgeon, beluga, and carp, bruiſed, ſalted, dried, and immerſed in oil, form the Ruſſian delicacy named caviar; this, and a ſimilar preparation from other fiſhes, were eaten in great quantities by the adherents of the Greek church, although Tournefort thought them deteſtable. The Roman luxury garum, which bore ſo high a price, conſiſted of the putrid entrails of fiſhes (firſt of the garus only) mixed with wine; and a ſimilar preparation is ſtill eaten in ſome parts of the eaſt. After this we ſhall not be ſurpriſed at hearing that the Arabs, Moors, Californians, and Ethiopians, eat locuſts; and that toads, graſshoppers, ſcorpions, and ſpiders, have ſerved for the food of man.

The aſſertion that all vegetable matters will ſerve us for food, muſt be taken with ſome limitation: for, beſides the poiſonous and medicinal productions of this kingdom, the fibrous and membranous parts of vegetables are clearly not digeſted, let them be ever ſo tender and ſoft. They are, however, digeſted by ſome other animals; but every man knows, from his own obſervation, that the ſkin of grapes or raiſins, &c. paſſes unchanged through the inteſtines. Oats will ſtill retain their power of germination, after going through the alimentary tube in horſes, if the huſk be not broken before they enter the ſtomach. Neither are all animal matters digeſtible; this is the caſe with cuticle, hair, horn, feathers, &c. which, accordingly, are thrown up in balls from the ſtomach of birds of prey. The indigeſtible nature of theſe matters probably ariſes from their being inorganic, or deſtitute of living powers.

It may alſo be mentioned as a curious fact, that the poiſonous juices of ſeveral animals, which, when infuſed into a wound, prove almoſt inſtantly fatal, may nevertheleſs be taken into the ſtomach, not only of many other animals, but even of the human ſubject, without the ſmalleſt detriment. Dr. Fordyce knew the black ſervant of an Indian merchant in America who was fond of ſoup made of rattle-ſnakes, in which he always boiled the head along with the reſt of the animal, without any regard to the poiſon. It has alſo been aſcertained, that the deadly ticunas, with which the American arrows are poiſoned, may be taken into the ſtomach with impunity. Neither are the animal or vegetable poiſons ſo eſſentially injurious to life as to exert their deleterious effects invariably. The conium maculatum, which is highly poiſonous to man, is taken in abundance, without injury, by goats: ſeveral other poiſonous vegetable productions are eaten by birds; and the cantharides are devoured by two kinds of inſect, whoſe juices are, nevertheleſs, perfectly mild.

Since man is diſtinguiſhed beyond all animals by the power of living in the moſt diſtant parts of the globe, under every variety of climate which this earth affords, his food could not be derived excluſively from either kingdom, ſince he inhabits regions that afford aliments only of one or the other ſort. He claims more juſtly than any other the title of an omnivorous animal; becauſe, on the one hand, he can revel in the vaſt variety of aliments drawn from the endleſs ſtores of the animal and vegetable kingdoms; while, on the other ſide, he can live healthy and ſtrong on a ſingle, and that the moſt ſimple form of food. Thus, in modern times, numerous examples occur of perſons living entirely on potatoes, cheſnuts, dates, &c. Some wandering Moors are confined almoſt entirely to gum Senegal (Mem. de l'Acad. des Sc. 1778.) The Kamtſchatkans, and other inhabitants of the ſea-ſhore, ſubſiſt wholly on fiſh; the ſhepherds, in the province of Caraccas, on the Oronoko, entirely on fleſh. Some barbarous tribes eat their meat raw.

Since, then, it appears that the ſtructure of the teeth, the joint of the lower jaw, and the form and ſtructure of the ſtomach and inteſtines, hold a middle rank, in the human ſubject, between the carnivorous and herbivorous; and that men have actually ſubſiſted in full health and ſtrength on one or the other kind only, or on a mixture of both ſorts of food, the concluſion that he is naturally deſigned to be omnivorous follows neceſſarily. We are the more diſpoſed to wonder

that

that this ſhould have been at all conteſted, when we find that ſeveral other animals are by no means ſo ſtrictly confined to one ſort of food, as not to derive a ſufficient nouriſhment from the other ſpecies; not to mention the numerous examples of omnivorous quadrupeds and birds; cows, horſes, and ſheep have been nouriſhed on fiſh and fleſh, fowls on animal food; and cats and dogs have learned to eat vegetables: and if we reflect, moreover, that thoſe animals which form the food of the carnivorous ſpecies are fed on vegetables, theſe circumſtances will admit of eaſy explanation.

Man has not been able to introduce ſo great a variety into his drink as into his ſolid food. Water alone, perhaps, ſupplies nine tenths of the human race; and as this ſeems prepared for us by the hand of nature, as all animals employ it, and it exceeds all other drinks in its properties as a diluent and ſolvent, we cannot doubt that it is the moſt wholeſome beverage: whether it is to be regarded merely as a diluent, or whether it be nouriſhing in itſelf, ſeems a matter of doubt; although there is little queſtion that life would be prolonged with the uſe of water beyond the period at which it would ceaſe without any food or drink. The fact, which has been proved by the experiments of Fordyce, that gold-fiſh will increaſe in weight in pure diſtilled water, and void fœces, ſeems deciſive in proving that thoſe animals are nouriſhed by it, and there can be no doubt that it affords nouriſhment to vegetables alſo. In almoſt all parts of the globe ſome fermented liquor has been prepared, poſſeſſing the power of inebriation by the alcohol which it contains; yet, undoubtedly, affording a certain portion of nouriſhment.

Some ſingular circumſtances have alſo been obſerved concerning drink. Several iſlands between the tropics, particularly in the Pacific ocean, have no freſh water; and its place is ſupplied by the milk of the cocoa-nut. Others drink ſea-water. An inſtance occurs, in the eſſays of the Edinburgh Medical Society, of a woman who lived for fifty years on whey only.

Digeſtion. The aliment introduced into the ſtomach accumulates there, and ſeparates the parietes of the organ, which are always contiguous in its empty ſtate. Here the ſtomach yields to the mechanical diſtenſion without reacting. Yet it ſeems not to be entirely paſſive; or, at leaſt, its coats apply themſelves by a kind of tonic movement to the accumulating matter. As the quantity of food increaſes, the greater curvature of the ſtomach advances forwards. Although this organ has been regarded in all times as the chief inſtrument of digeſtion, it ſeems, in fact, to perform only a preparatory office; and not to accompliſh the grand and eſſential phenomenon of this function, namely, the ſeparation of the nutritive and excrementitious parts of the aliment. Yet the food in its cavity is prepared for that ſeparation; it is rendered more fluid, it experiences a great alteration, and is converted into a ſoft homogeneous pap, called *chyme*. Since the latter ſubſtance poſſeſſes new properties, it is evident that the food has undergone ſome changes in the ſtomach, and that the ingredients of which it was compoſed, have entered into new combinations. What then is the agent of this converſion? In other words, what is the action of the ſtomach on the food?

Various hypotheſes have been framed in order to anſwer this queſtion. The father of medicine, and the ancients in general, conſidered digeſtion as effected by *coction*. They did not by this term mean to deſignate any change ſimilar to that which ſubſtances experience when boiled: the temperature of the ſtomach is manifeſtly inadequate to the effect. Moreover, cold blooded animals digeſt as well as thoſe with warm blood; and the heat of fever, inſtead of invigorating, entirely deſtroys the digeſtive power. Coction, in the language of the ancients, means the alteration, maturation, and animalization of the food in the ſtomach. It is clear that the natural warmth of the part aſſiſts and facilitates theſe changes. Spallanzani's experiments on artificial digeſtion ſhew that the gaſtric juice has no more effect than common water in ſoftening and diſſolving the food, when the temperature is below 21°: on the contrary, that its agency is very conſiderable, when the mercury riſes to 30 and upwards above the freezing point. In cold blooded animals the proceſs is always much ſlower than in the warm blooded.

The authors and partiſans of the ſyſtem of *fermentation* have recognized in the food, when received into the ſtomach, a ſpontaneous inteſtine motion; by virtue of which, it paſſes into a new order of combinations. As we accelerate the fermentative proceſs, by adding to thoſe ſubſtances which are undergoing it, a portion of the ſame matter that has already fermented, ſome have ſuppoſed a ſort of leaven conſtantly exiſting in the ſtomach, formed by a ſubtle acid, or conſiſting of a ſmall portion of food remaining behind from the preceding digeſtion. The nature and cauſes of fermentation were imperfectly underſtood when this explanation was adopted. "All that could be meant, ſays Dr. Thomſon, by ſaying, that the converſion of food into chyme in the ſtomach is owing to fermentation, was merely that the unknown cauſe, which acted during the converſion of vegetable ſubſtances into wine or acid, or during their putrefaction, acted alſo during the converſion of the food into chyme, and that the reſult in both inſtances was preciſely the ſame. Accordingly, the advocates for this opinion attempted to prove that air was conſtantly generated in the ſtomach, and that an acid was conſtantly produced; for it was the vinous and acetous fermentations which were aſſigned by the greater number of phyſiologiſts as the cauſe of the formation of chyme. Some, indeed, attempted to prove that it was produced by the putrefactive fermentation; but their number was inconſiderable, compared with thoſe who adopted the other opinion.

"Our ideas reſpecting fermentation are now ſomewhat more preciſe: it ſignifies a ſlow decompoſition, which takes place when certain animal or vegetable ſubſtances are mixed together at a given temperature, and the conſequent production of particular compounds. If, therefore, the converſion of the food into chyme be owing to fermentation, it muſt evidently be totally independent of the ſtomach, any further than as it ſupplies temperature; and the food would be converted into chyme exactly in the ſame manner, if it were reduced to the ſame conſiſtence, and placed in the ſame temperature out of the body. But this is by no means the caſe; ſubſtances are reduced to the ſtate of chyme in a ſhort time in the ſtomach, which would remain unaltered for weeks in the ſame temperature out of the body. This is the caſe with bones; which the experiments of Stevens and Spallanzani have ſhewn to be ſoon digeſted in the ſtomach of the dog. Further, if the converſion of the food into chyme were owing to fermentation, it ought to go on equally well in the ſtomach and œſophagus. Now, it was obſerved long ago by Ray and Boyle, that when voracious fiſhes had ſwallowed animals too large to be contained in the ſtomach, that part only which was in the ſtomach was converted into chyme, while that which was in the œſophagus remained entire.

If, too, the converſion were owing to fermentation, it ought always to take place equally well, provided the temperature be the ſame, whether the ſtomach be in a healthy ſtate or not. But it is well known that this is not the caſe. The formation of chyme depends very much on the ſtate of the ſtomach. When that organ is diſeaſed, digeſtion is conſtantly ill performed. In theſe caſes, indeed, fermentation ſometimes

appears, and produces flatulence, acid eructations, &c. which are the well-known ſymptoms of indigeſtion. Theſe facts, which have been long known, are incompatible with the ſuppoſition that the formation of chyle is owing to fermentation; accordingly, that opinion has been for ſome time abandoned, by all thoſe at leaſt who have taken the trouble to examine the ſubject."

With as little reaſon has digeſtion been conſidered a ſpecies of putrefaction, or ſpontaneous change of the animal and vegetable food. Not to mention that digeſtion never exhibits any appearance of ammoniacal products, which are the moſt ſtriking reſults of putrefaction, we ſhall find that the digeſtive organs have the power of reſtoring putrid meats to a ſound ſtate, or at leaſt of arreſting the putrefaction of ſubſtances ſubmitted to their action. Serpents are enabled, by the great dilatability of their œſophagus, and the wide ſeparation of their equally moveable jaws, to ſwallow animals larger than themſelves. Several days are conſumed in digeſting theſe; and, during the proceſs, that part of the animal which is ſubmitted to the action of the ſtomach, is perfectly ſweet, and in a more or leſs advanced ſtate of diſſolution, while the portion in the œſophagus preſents appearances of commencing putrefaction. In ſpite of the heat and moiſture of the part, the aliment does not ſtay long enough in the ſtomach for putrefaction to commence. Moreover, Spallanzani, Hunter, and other phyſiologiſts, have found that putrid fleſh, when taken accidentally, or given purpoſely to animals, loſt its putrid characters in the ſtomach, previouſly to its digeſtion.

Fermentation was the ſyſtem of the chemiſts; trituration was that of the mathematical phyſiologiſts; who compared the changes effected on a ſubſtance in a mortar by the peſtle of the apothecary, to thoſe which the food undergoes in the ſtomach. But what analogy could ever have been conceived to exiſt between the forcible attrition of a ſubſtance againſt a reſiſting plane, and the gentle periſtaltic motion of the fibres of the ſtomach? This opinion could have been held no longer, when it was perceived that chyme differed entirely from the food that had been taken; that is to ſay, that if the ſame food were triturated mechanically out of the body, and reduced to pap of preciſely the ſame conſiſtence with chyme, it would not poſſeſs the ſame properties with chyme. For, whenever this fact was known, it muſt be evident that the food had undergone changes in its compoſition. The fact that various fruits, as grapes, currants, raiſins, &c. which are covered with a membranous coat, will paſs through the inteſtines unchanged, if the covering be not broken in maſtication, and that often, particularly in animals, ſlender worms remain unaltered in the ſtomach, ſhews that the food can experience only a very ſlight compreſſing force in its paſſage. But the direct experiments of Stevens, Reaumur, and Spallanzani, demonſtrated that chyme is not owing to trituration; for, on encloſing different kinds of food in metallic tubes and balls full of holes, in ſuch a manner as to ſcreen them from the mechanical action of the ſtomach, they found that theſe ſubſtances, after having remained a ſufficient time in the ſtomach, were converted into chyme, juſt as if they had not been encloſed in ſuch tubes.

The mode in which digeſtion is effected in the gizzard of the gallinaceous birds, is the moſt plauſible argument in favour of trituration. In them the food, after being macerated in the crop, deſcends into the gizzard, whoſe vaſt muſcular ſtrength enables it to ſupply the place of organs of maſtication. (See the article BIRDS.) The trituration which it experiences here is aided by ſtones which the animal ſwallows; and its effects are truly ſurpriſing. Globes of glaſs or cryſtal are pulverized; bullets or metallic tubes are flattened, &c. Theſe effects are analogous to thoſe of maſtication in the human ſubject; and the true digeſtion is completed by means of a fluid ſecreted in certain glands at the termination of the œſophagus. The wide difference of ſtructure between theſe gizzards and the human ſtomach ſhould have ſhewn the abſurdity of applying inferences drawn from what happens in the one, to the other.

Pitcarne calculated the power of the ſtomach as equal to 12,951lbs.; and that of the diaphragm and abdominal muſcles, which compreſs the ſtomach in the alternate motions of reſpiration, at 248,235lbs. What does ſuch an abſurd and exaggerated calculation ſhew, but that the vain apparatus of axioms, definitions, ſcholia, and corollaries, which have been introduced into works foreign to the nature of geometry, has only ſerved to entrench vague, confuſed, and falſe notions behind impoſing and reſpected forms? The introduction of the hand into the abdomen of a living animal, or of the finger into a wound of the ſtomach, is ſufficient to ſhew that the force with which that organ acts on its contents does not exceed a few ounces.

The learned and laborious Haller ſuppoſed that the food was merely diluted and ſoftened by the gaſtric juice; he conceived that this *maceration* was favoured and accelerated by the warmth of the part, by the commencement of putrefaction, and by the gentle, but continual motions, by which the aliment is agitated. Maceration ſurmounts at length the cohefive force of the moſt ſolid ſubſtances; but it never changes their nature, and cannot therefore be the agent of digeſtion. This opinion was chiefly formed on the analogy or ruminating animals; in whom the imperfectly maſticated food is conveyed into an ample receptacle called the firſt ſtomach, or paunch, where it is truly macerated, and perhaps undergoes incipient fermentation. It is brought back from this cavity to the mouth to be again chewed, after which it deſcends into the ſecond and third, and laſtly into the fourth, or true digeſtive ſtomach. Here the whole ſtructure is ſo totally different from that of the human ſubject, that we may juſtly proteſt againſt drawing any analogy between the two caſes.

The formation of chyme, then, is owing to ſome peculiar proceſs taking place in the ſtomach; and it has been concluded from the experiments of Stevens, Reaumur, Spallanzani, Scopoli, Brugnatelli, Carminati, and others, that its formation is brought about by the action of a particular liquid ſecreted by the ſtomach, and for that reaſon called *gaſtric juice*.

No organ perhaps receives a greater number of veſſels, in proportion to its bulk, than the ſtomach; and hence we conclude, that this large ſupply is not merely deſigned for the nutrition of its ſubſtance, but alſo to furniſh the materials of ſome ſecretion. The fluid thus formed is the gaſtric juice, which is probably poured out moſt abundantly when the preſence of food in the ſtomach irritates that organ, and invites an afflux of blood from its numerous arterial tubes. It ſeems to be produced directly from the exhaling arteries, without any intermediate ſecretory apparatus. It is mingled with the mucus furniſhed by the glands of the villous coat, and thus it becomes viſcous, like ſaliva, with which, on the whole, it has conſiderable analogy. It is extremely difficult to obtain it pure for the purpoſes of analyſis; and even, if we could ſucceed in depriving the ſtomach of all reſidue of the food which might impair the purity of the gaſtric juice, we ſhould not be able to prevent the admixture of a ſmall portion of bile, which, entering at the pylorus, tinges the internal coat near that opening, and imparts a certain bitterneſs to the juices of the ſtomach.

Dr. Thomſon, in his ſyſtem of chemiſtry, ſeems to place very

very little reliance on the accuracy of the analyſes which have hitherto been made of the gaſtric juice. "It is," ſays he, "different in different animals, but it is a very difficult, if not an impoſſible taſk, to obtain it in a ſtate of purity. Various attempts have, indeed, been made by very ingenious philoſophers to procure it; but their analyſis is ſufficient to ſhew us that they have never obtained it in a ſtate of purity. The methods which have been adopted to procure gaſtric juice, are, firſt, to kill the animal whoſe gaſtric juice is to be examined, after it has faſted ſome time. By this method Spallanzani collected 37 ſpoonfuls from the two firſt ſtomachs of a ſheep. It was of a green colour, undoubtedly owing to the graſs which the animal had eaten. He found alſo half a ſpoonful in the ſtomach of ſome young crows, which he killed before they had left their neſt.

Small tubes of metal, pierced with holes, and containing a dry ſponge, have been ſwallowed by animals; and when vomited up, the liquid imbibed by the ſponge is ſqueezed out. By this method Spallanzani collected 481 grains of gaſtric juice from the ſtomachs of five crows. A third method conſiſts in exciting vomiting in the morning, when the ſtomach is without food. Spallanzani tried this method twice upon himſelf, and collected one of the times 1 oz. 32 gr. of liquid; but the pain was ſo great, that he did not think proper to try the experiment a third time. Mr. Goſſe, who could excite vomiting whenever he thought proper, by ſwallowing air, has employed that method to collect gaſtric juice. In any of theſe means it muſt be contaminated by the admixture of ſaliva, mucus, bile, food, &c. It may, too, be queſtioned, whether any gaſtric juice at all can be obtained by theſe methods; for as the uſe of that fluid is to convert the food into chyme, in all probability it is only ſecreted, when food is preſent.

According to Brugnatelli, the gaſtric juice of carnivorous animals, as hawks, kites, &c. has an acid and reſinous odour, is very bitter, and not at all watery; and is compoſed of an uncombined acid, a reſin, an animal ſubſtance, and a ſmall quantity of muriate of ſoda. In herbivorous animals, on the contrary, as goats, ſheep, &c. it is very watery, a little muddy, has a bitter ſaltiſh taſte, and contains ammonia, an animal extract, and a pretty large quantity of muriate of ſoda. Carminati found the ſame ingredients; but ſuppoſed that the ammonia had been formed by the putrefaction of a part of the food, and that the gaſtric juice in theſe animals is therefore of an acid nature.

In man it has ſometimes been found of an acid nature, at other times not. The experiments of Spallanzani ſhew that this acidity is owing to the food. He never found any acidity in birds of prey, ſerpents, frogs, or fiſhes. Crows gave an acidulous gaſtric juice only when fed on grain; and he obſerved the ſame fact in dogs, herbivorous animals, and domeſtic fowls. Carnivorous birds threw up pieces of ſhell and coral without alteration; but theſe ſubſtances were ſenſibly diminiſhed in the ſtomachs of hens, even when encloſed in perforated tubes. Spallanzani ſwallowed calcareous ſubſtances encloſed in tubes; and when he fed on vegetables and fruits, they were ſometimes altered, and a little diminiſhed in weight, juſt as if they had been put into weak vinegar; but when he uſed only animal food, they came out untouched. According to this philoſopher, whoſe experiments have been by far the moſt numerous, the gaſtric juice is neither acid nor alkaline. When poured on the carbonate of potaſh, it cauſes no effervescence.

The ſame concluſion concerning the influence of the food on the nature of the gaſtric juice, is rendered ſtill more indiſputable by the experiments of Dumas (Principe de Phyſiologie, tom. 4. ch. 9.) Having procured gaſtric juice from a dog by means of ſponge, in the mode employed by Spallanzani, he found that it did not change the vegetable blue; nor affect lime water; nor effervesce with alkalies. After feeding the animal with vegetables for fifteen days, the gaſtric juice ſhewed indiſputable marks of acidity. A diet of animal food was now ſubſtituted in place of the vegetable, for the ſame length of time, when inſtead of marks of acidity, there were rather indications of an alkaline tendency. When a mixed diet was employed, no predominant quality appeared: the gaſtric juice was faint, inſipid, thick and viſcous.

With reſpect to the ſubſtances contained in the ſtomach, only two facts have been perfectly aſcertained: the firſt is, that the juice contained in the ſtomach of oxen, calves, and ſheep, invariably contains uncombined phoſphoric acid, as Macquart and Vauquelin have demonſtrated. The ſecond, that the juice contained in the ſtomach, and even the inner coat of the ſtomach itſelf, has the property of coagulating milk and the ſerum of the blood. Dr. Young found that ſeven grains of the inner coat of a calf's ſtomach, infuſed in water, gave a liquid which coagulated more than 100 ozs. of milk; that is to ſay, more than 6857 times its own weight; and yet, in all probability, its weight was not much diminiſhed.

What the ſubſtance is that poſſeſſes this coagulating property, has not yet been aſcertained; but it is evidently not very ſoluble in water; for the inſide of a calf's ſtomach, after being ſteeped in water for ſix hours, and then well waſhed with water, ſtill furniſhes a liquor, on infuſion, which coagulates milk: and Dr. Young found that a piece of the inner coat of the ſtomach, after being previouſly waſhed with water, and then with a diluted ſolution of carbonate of potaſh, ſtill afforded a liquid, which coagulated milk and ſerum.

The moſt remarkable property of gaſtric juice, is the very ſingular activity of its ſolvent power. The hardeſt bones yield to its influence; and it acts as a real menſtruum on thoſe ſwallowed by the dog, uniting with their organiſed and gelatinous parts, and leaving a calcareous reſidue, which is the material of thoſe excrementitious concretions to which the older chemiſts gave the ridiculous name of album Græcum. The ſolvent energy of this fluid is in an inverſe ratio to the muſcular ſtrength of the coats of the ſtomach; and where theſe are the thineſt and weakeſt, it poſſeſſes the greateſt force and activity. In the numerous claſs of zoophytes it is the ſole agent of digeſtion, as the food undergoes no preliminary preparation: this, indeed, is alſo the caſe in many other inſtances. It is always more active when aſſiſted by warmth, as Trembley obſerved in the polype, which, according to his obſervations, digeſted in twelve hours in the ſummer, what occupied three days in colder times. In the actinea and holothuria it deſtroys even the ſhells of muſcles, which thoſe animals ſwallow. It attacks the ſurface of bodies, unites to the particles of them, which it carries off, and from which it cannot be ſeparated by filtration. It operates with more energy and rapidity, the more the food is divided. The aliment is not merely reduced to very minute parts; its taſte and ſmell are quite changed; its ſenſible properties are deſtroyed, and it acquires new and very different ones. It does not act as a ferment; ſo far from it, that it is a powerful antiſeptic, and even reſtores fleſh already putrified. Only a few air bubbles make their eſcape, which adhere to the alimentary matter, and buoy it up to the top, and are probably extricated by the heat of the ſolution.

However powerfully the gaſtric juice may act in diſſolving alimentary ſubſtances, it does not affect the coats of the ſtomach itſelf; which probably owe their power of reſiſtance to their vitality. The lumbrici, which are very tender, are not

not affected for the ſame reaſon; yet, when the ſtomach is dead, it yields, like other matter, to the gaſtric juice, and in particular caſes becomes ſoftened, and partly deſtroyed. This circumſtance was firſt noticed by Mr. Hunter, and the caſes in which it has happened are thoſe of ſudden deaths, where the perſon was previouſly in good health, and had lately eaten. In ſome, confeſſedly rare examples, a large hole has been found in the ſtomach from this cauſe, with the margins ragged and ſoft. As the facts mentioned by Mr. Hunter have been queſtioned, the writer of this article can add one, in which he found the great end completely deſtroyed in a child. In animals it is by no means rare to find the ſtomach even very conſiderably diſſolved in this way; and we can eaſily kill them under circumſtances in which the effect is likely to take place. In the human ſubject the great end of the ſtomach will often be found pulpy and ſoft on its internal ſurface, although it be not actually diſſolved through.

We have already noticed the coagulating power of the calf's ſtomach: it is found that coagulable animal fluids, as milk or jelly, introduced into the ſtomach, are coagulated before they are digeſted. This fact is obvious with reſpect to the milk vomited by ſuckling children. They muſt afterwards be diſſolved like the more ſolid parts of the food.

The proof of the facts already ſtated concerning the action of the gaſtric juice, is derived from experiments, in which food encloſed in perforated tubes taken into the ſtomach, and returned again by vomiting, has been completely changed into chyme. Spallanzani has repeated his reſearches almoſt unneceſſarily on this point, in the various claſſes of animals, and uniformly with the ſame reſult as to the performance of digeſtion by a ſolvent fluid. Similar reſearches have alſo been inſtituted on the human ſubject, with the ſame event. It has been found, too, that digeſtion could be imitated out of the body, by means of gaſtric juice obtained in the methods explained above; that alimentary ſubſtanees, expoſed to its action in the temperature of the human body, were diſſolved, while they remained unchanged in water under the ſame circumſtances.

Dr. Stevens met with a very favourable opportunity of aſcertaining the action of the gaſtric juice on ſubſtances encloſed in tubes and ſwallowed, in a man who had the power of ſwallowing ſtones. Twenty-eight gr. of pork and cheeſe were entirely diſſolved, when the tubes were voided in 43 hours: the ſame was aſcertained of parſnip and potatoe, boiled ſalt, herring, and roaſt turkey. Grain covered by its huſk, was unaltered: neither was bone affected. Leeches and earth-worms were completely diſſolved. In the ſtomach of a dog 3 ſcruples 16 gr. of ivory loſt 2 ſcruples: and bone was ſenſibly affected. Cartilage was not changed, nor fat ſo much as lean.

The gaſtric fluid then will exert its influence on the dead ſtomach, and it will even act on alimentary matters out of the body. Yet we muſt not completely identify theſe caſes with that of digeſtion in the ſtomach; we are not to regard that organ as a chemical veſſel, in which decompoſitions and recombinations are going on; we muſt take into conſideration the living powers of the part, and we ſhall find, that the ſecretion of gaſtric juice is ſubject to the influence of theſe, and that it requires the free and continued action of the nerves of the part. The ligature of the par vagum, the uſe of narcotics and opium, profound meditation, or violent emotions of the mind, will interrupt or ſuſpend digeſtion. Dumas has performed ſeveral experiments on this ſubject; he found the gaſtric ſecretion diminiſhed by introducing opium into the ſtomach, alſo by acids and alcohol; increaſed by volatile alkali, emetic tartar, and corroſive ſublimate; and interrupted or ſuſpended by cauſes that affected the nervous ſyſtem in general, as violent pain. When the natural functions of the part were thus diſordered, fermentation and putrefaction took place in the aliment. Indeed, the changes which the food undergoes in the ſtomach, differ eſſentially from any which chemical means can produce; no artificial proceſs can imitate the formation of chyme; no ſolution, analyſis, or combination, will ever enable the chemiſt to form or extract that nutritive fluid common to all animals, but poſſeſſing ſpecific characters in each. Without, however, pretending to admit or to exclude the poſſibility of bringing, one day or other, the converſion of aliment into the nutritive fluid, under the general laws of chemiſtry, we may at leaſt note certain circumſtances which belong inconteſtibly to vital phenomena. 1ſt. Digeſtion varies according to the nature and diſpoſition of the animal in which it is performed, a circumſtance contrary to the uniformity of chemical reſults. 2dly. It varies according to individual peculiarities, one perſon digeſting well what would diſagree with another, &c. 3dly. The taſte, appetite, and fancy, influence the proceſs conſiderably; an antipathy conceived againſt even a wholeſome food, will prevent its digeſtion. If the living powers of the ſtomach be ſtrong, the food will be perfectly digeſted; while, under contrary circumſtances, the ſame food would undergo chemical changes. Hence, if too large a quantity, or an indigeſtible ſort of food, or ſuch as the ſtomach has not been accuſtomed to, be taken into a weak ſtomach, it will be converted into a matter, which may be taken up with the chyle, and produce noxious effects on the ſyſtem, as too much ſalted animal food does in ſailors; or it may be converted into ſubſtances noxious to the ſtomach and inteſtines, as in heart-burn, vomiting, &c.; or its effects on the organs of digeſtion may be noxious to the whole ſyſtem, cauſing fever, &c. On the other hand, ſtrong ſtomachs, and particularly ſuch as are habituated to any particular kind of food, derive perfect nouriſhment from ſuch food, whatever it be. Thus, a Laplander lives upon reindeer alone, without intermixing, for moſt part of the year, any vegetable food; and others live on ſhell-fiſh, dead and putrid ſeals and whales, &c. Hence, particular kinds of food are not more capable, in themſelves, of affording good chyle; but particular ſpecies muſt be adapted to the ſtate of the digeſtive organs, in order to be that which is moſt proper or wholeſome; or, in other words, no food is, in itſelf, wholeſome or unwholeſome, but as it is compared with the preſent ſtate of the ſtomach and organs of digeſtion.

Dr. Fordyce, in his Treatiſe on Digeſtion, argues againſt the opinion which aſcribes digeſtion to any ſolvent fluid formed in the ſtomach, and he appears to conſider it as a chemical proceſs, effected by the living powers of the ſtomach. He obſerves, that the ſubſtances employed for food, yield the ſame elements on analyſis as chyle, and that food and chyle differ only in the mode of combination of theſe elements. "Digeſtion (ſays he, p. 166) is performed on ſubſtances containing all the elements of chyle. Theſe ſubſtances in the ſtomach, and other organs of digeſtion, have their elements ſeparated from one another by the effects of the ſtomach, and other organs of digeſtion upon them, occaſioning in them a decompoſition and recombination of their elements into a new ſubſtance."

Reſt of the body ſeems an eſſential condition to the right performance of digeſtion; exerciſe interrupts it, and this has been proved by direct experiment on two dogs, who were fed at the ſame time. One was allowed to lie down quiet, while the other was taken out hunting, and they were then both killed. The aliment in the dog who had been exerting himſelf was unchanged.

The

The food remains in the ſtomach a longer or ſhorter time, according as its nature diſpoſes it to yield more or leſs readily to the action of that organ. Goſſe, of Geneva, found, by experiments on himſelf, that animal and vegetable fibres, concrete albumen, the white and tendinous parts of animals, paſtes made with fat and buttery ſubſtances, unfermented, or ſlightly fermentable matters, remain longer in the ſtomach than the gelatinous parts of animals and vegetables, fermented bread, &c. That the latter only required an hour for their diſſolution, while the former were hardly diſſolved in ſeveral hours. It ſeems hardly poſſible to lay down any general rule, on account of the great variety of alimentary articles. It ſhould appear, that the various parts of a meal go off in proportion as they are digeſted; water and mild fluids muſt paſs very quickly through the ſtomach, for they are ſeparated by the kidneys ſo ſoon after drinking, as to have induced many phyſiologiſts to ſuſpect a ſhorter communication between the ſtomach and kidneys than by means of the inteſtines, lacteals, and general circulation. According to Viridet, watery fluids paſs in half an hour; ripe fruits, light meats and bread, in from three to five hours; harder meats not till the 7th or 8th hour. In wounds of the inteſtines, milk has come out in half an hour, and ſoon after in a coagulated ſtate. In another caſe of that kind, beer appeared in an hour; ripe fruits and vegetables in two hours; meat and bread in nine hours. Theſe circumſtances, however, would be influenced by the unnatural ſtate of the ſubject. "I have obſerved (ſays Haller) what paſſed in my own perſon, when my digeſtion was not good, and when eructations, impregnated with the taſte of the food, aſcended from time to time. I ſtill perceived a kind of commotion in the meat, which my ſtomach did not act on well, four hours after the meal: this gradually ſubſided, and in ſix hours after a moderate dinner, my ſtomach was empty, and pure air alone aſcended." Elem. Phyſiol. tom. 6. p. 281.

An intereſting caſe of fiſtulous opening in the ſtomach, communicating externally, and related by Richerand in his "Nouveaux Elemens de Phyſiologie," throws much light on the ſubject of digeſtion. The aperture, more than 18 lines long, and an inch broad, expoſes the interior of the ſtomach. It came on in conſequence of an injury, and had exiſted for many years. At the admiſſion of this patient into the Hoſpice de la Charité, ſhe ate three times as much as ordinary perſons, made about a pint of urine daily, and had a ſtool once in three days. Three or four hours after a meal, an irreſiſtible feeling compelled her to remove the dreſſings of the fiſtula, and to allow the eſcape of the food, which the ſtomach could no longer contain. The contents came out quickly, accompanied by more or leſs air. They poſſeſſed a faint odour, but had neither acid nor alkaline properties; for the greyiſh paſte, of which they conſiſted, when diluted with diſtilled water, did not affect the vegetable blue. The digeſtion was often far from complete, yet frequently the odour of wine was deſtroyed, and bread was reduced to a ſoft, viſcous, and thick ſubſtance, reſembling fibrine recently precipitated by the acetous acid, and ſwimming in a ſtringy fluid of the colour of ordinary ſoup. The experiments made on this half-digeſted food, at the Ecole de Medecine, ſhewed, that the changes which it had undergone were an increaſe of gelatine, the formation of a ſubſtance like fibrine, and of a conſiderable proportion of muriate and phoſphate of ſoda, and phoſphate of lime. This patient could never ſleep until after ſhe had emptied her ſtomach, and waſhed it out by drinking infuſion of camomile. In the morning it contained a ſmall quantity of thick and frothy liquid, analogous to ſaliva, which did not affect the vegetable blue, and contained parts of more conſiſtence, and even compleatly opaque albuminous flocculi mingled with the liquid portion. The reſults of chemical experiment on this liquid, were ſimilar to thoſe obtained from the ſpittle.

This patient, thin and emaciated, dragged on a feeble and languiſhing exiſtence, ſupported by the ſmall quantity of food which paſſed through the pylorus, to receive the influence of the biliary ſecretion, the action of which, on the chyme, is eſſential to the ſeparation of its nutritive portions. The ſmall quantity of nouriſhment that could be taken up by the abſorbents of the ſtomach, contributed very little to ſupport the frame; and the patient, therefore, was circumſtanced like thoſe who have a diſeaſed pylorus, which, refuſing to yield, when digeſtion is accompliſhed, cauſes the food to be vomited up. While the diſſolution of the food is proceeding, both orifices of the ſtomach are cloſed; no gas, diſengaged from the food, aſcends through the œſophagus, except from imperfection in the proceſs. Slight ſhiverings are felt; the pulſe becomes quick and firm; and the vital powers ſeem to be diminiſhed in the body at large, that they may be increaſed in the organ of the digeſtive proceſs. Soon the coats of the ſtomach begin to act; the circular fibres contract in different parts; theſe periſtaltic oſcillations, at firſt vague and irregular, are repeated from above downwards, and from left to right; that is, from the œſophageal towards the pyloric orifice. The longitudinal fibres ſhorten it in its long diameter, ſo as to approximate the two orifices. In theſe motions the ſtomach is elevated on the pylorus, ſo as to efface the angle which it forms at the commencement of the duodenum, and thereby to facilitate the food's paſſage.

The pyloric ſphincter remains contracted while digeſtion is going on, and prevents the paſſage of thoſe portions which are not ſufficiently ſubdued. Endowed, probably, with a peculiar and delicate ſenſibility, the pylorus, as its name imports, may be regarded as a vigilant ſentinel, obſtructing the egreſs of all which is not duly changed. Hence ſeveral authors have obſerved, that the aliments do not quit the ſtomach in the order of their admiſſion into that cavity, but according to their greater or leſs digeſtibility; we might, therefore, aſſert that there is a real ſeparation of the food in the ſtomach. The moſt ſpeedily diſſolved aliments are directed towards the pylorus, which yields to them, and rejects thoſe, which being inſufficiently digeſted, do not convey a ſuitable impreſſion to the part. The paſſage of coins may be objected to this delicate ſenſibility of the pyloric ſphincter: but let it be remembered that theſe, and other indigeſtible ſubſtances, remain in the ſtomach ſome time before they paſs, are repeatedly preſented to the pylorus, and thus accuſtom that part to their contact. The gaſtric ſyſtem may be compared in this reſpect to a ſecretory gland; and as the excretory tubes, poſſeſſing a ſpecies of *elective* ſenſibility, do not admit the ſecreted fluid until it has been duly prepared in the glandular parenchyma; ſo the pylorus will not allow the food to paſs into the inteſtine, which may be regarded as the excretory duct of the ſtomach, until it has been ſufficiently elaborated in that organ.

As the ſtomach frees itſelf the ſpaſm of the ſkin ceaſes, a gentle warmth ſucceeds; the pulſe becomes fuller, and the inſenſible tranſpiration increaſes. Digeſtion, therefore, produces a general movement, analogous to a febrile attack; and this effect, remarked by the ancients, is particularly obſervable in females of great ſenſibility. The action of the ſtomach does not ceaſe until it has entirely expelled its contents. The gaſtric juice, no longer called for by the preſence of food, is poured out in ſmaller quantity, or perhaps not at all; and the parietes, brought into contact with each

each other, are lubricated by the mucous ſecretions of the part.

For further obſervations on the action of the ſtomach, on vomiting, on its ſympathies with other organs, &c. See STOMACH.

Chylification.

The aliments having ſuffered the firſt degree of aſſimilation, quit the ſtomach, paſs into the duodenum, and there experience new changes, as eſſential as thoſe which they underwent in the ſtomach; this proceſs is named chylification. The food conſiſts now of a half liquid pultaceous maſs, with a conſiderable mixture of matter foreign to the purpoſe of nutrition, the groſs reſidue of its decompoſition. The latter part is only fit to be expelled; and the action of the inteſtines conſiſts in extracting from it the nutritive fluid, in ſeparating the excrementitious portion, and in forming a mild, white, emulſive, and highly nutritive liquor, which is to be abſorbed by the lacteals and conveyed by them into the circulating ſyſtem. We may indeed affirm, ſince the chief end of digeſtion conſiſts in the ſeparation of the nutritive ſubſtance into two parts, an excrementitious and a chylous portion, that the duodenum, in which that ſeparation is effected, is its principal organ. The moſt attentive examination of the greyiſh chyme, as it leaves the ſtomach, diſcovers to us nothing but a ſoft homogeneous pap; and the abſorbents of that organ never contain, like thoſe of the inteſtines, true chyle. The duodenum may, in truth, be regarded as a ſecond ſtomach, as it is diſtinguiſhed from the reſt of the ſmall inteſtine by being ſituated externally to the peritoneum, by its magnitude, by its fixed curves, large number of valvulæ conniventes and lacteals; and particularly by its receiving the terminations of the pancreatic and biliary ducts. All theſe peculiarities retard the courſe of the alimentary ſubſtance, and prolong the term of its expoſure to the action of the laſt-mentioned fluids.

The irritation of the chyme in the duodenum is tranſmitted to the liver and gall-bladder, and induces an increaſed flow of hepatic and cyſtic bile diluted by the fluid of the pancreas, which probably participates in the general irritation and increaſed ſecretion of all the gaſtric organs. This mixed pancreatico-biliary fluid, poured on the chymous maſs, penetrates, dilutes, and animalizes it; ſeparates the chyle from the excrementitious part, and precipitates from it whatever is not nutritious. In this proceſs the bile itſelf ſeems to ſeparate into two portions. Its oily, colouring, and bitter part combines with the excrement, and imparts to it, thoſe ſtimulating properties, by means of which it excites the action of the alimentary tube; while the albuminous and ſaline portions mixed with the chyle, and being abſorbed with it, re enter the circulating ſyſtem. In fact, the contents of the ſmall inteſtine exhibit two very diſtinct ſubſtances after the admixture of the pancreatico-biliary fluid; one is a whitiſh milky matter, found at the ſurface, and adhering to the inteſtine; the other, more abundant, is yellowiſh: and when digeſtion is well performed, contains no traces of the nature of the food. A further account of the pancreatic and biliary fluids will be found under PANCREAS, LIVER, and BILE.

There is probably another fluid, beſides thoſe now enumerated, concerned in the buſineſs of chylification; a ſecretion from the villous coat of the inteſtines, ſuppoſed to be analogous to that of the ſtomach, and named *ſuccus inteſtinalis*. There muſt alſo be a conſiderable effuſion of mucus into the ſmall inteſtines, as the glands of that nature abound in the inteſtinal coats, particularly towards the latter portion of the tube. All, however, that we know on the ſubject of the inteſtinal fluid is mere matter of ſpeculation, derived from analogy and conjecture, and unſupported by direct experiment and obſervation, which the very nature of the ſubject ſeems entirely to preclude.

The action of the inteſtines is not confined to a change in the external and phyſical qualities of the food; it affects alſo their internal chemical properties. The developement of a gelatino-mucus ſubſtance, the formation of ſeveral ſalts, the diminution of acids in general, and of the carbonic acid in particular, an increaſe of azote and hydrogen, and the production of the principle of ſugar, are the eſſential changes which the food undergoes in the inteſtines. Yet the united agencies of the ſtomach and inteſtinal tube do not always ſucceed in changing the nature of the various matters ſubmitted to their action. The qualities of the food often affect very ſenſibly the chyle, blood, urine, milk, &c. Indigo tinges the chyle of a blue colour. The urine, ſweat, and milk are affected by the colour, odour, taſte, or medicinal qualities of rhubarb, ſcammony, violets, and other vegetable matters. The fat of fowls becomes infected with the ſmell of garlic; the fleſh of ſome birds is purgative, when they feed on particular vegetables; and the fiſhy taſte of ſuch as uſe fiſh for their food, is well known.

Of the effect produced by the inteſtines in the function of aſſimilation, we may obſerve, as we did of that ſhare of the proceſs performed in the ſtomach, that it is a living action, explicable only by means of the vital powers. Theſe regulate and modify the changes and combinations of the food; and hence the matter extracted from the aliment poſſeſſes a ſpecific character derived entirely from the properties of life. Hence the mixture of ſaliva, gaſtric juice, bile, and pancreatic liquor, with the food, out of the body, would never form chyle, nor any thing like it.

Action of the ſmall Inteſtine.

The alimentary maſs, ſeparated in the duodenum, in the manner already deſcribed, into two portions, enters the jejunum, and ſubſequently the ilium. Its paſſage is retarded by the numerous curvatures of the canal, which ſome phyſiologiſts, indulging in a poetic ſtrain, have compared to the windings of a ſtream enriching the ſoil through which it meanders. Theſe retain the aliment, in order that the chyle, expreſſed by the periſtaltic contraction of the inteſtines, may be repeatedly preſented to the inhalant orifices of the lacteals; which are particularly numerous on the ſurface of the valvulæ conniventes. The paſſage of the inteſtinal contents is not only retarded by theſe projections; but, as the contraction of the tube forces them into the alimentary maſs, the lacteals may be ſaid to ſeek in its interior the particles fit for abſorption.

The number of valves diminiſhing with that of the abſorbing veſſels, towards the lower part of the canal, the progreſs of the food is gradually accelerated in proportion as its nutritive parts are removed. The inteſtinal mucus, ſecreted more abundantly in this part, envelopes it and facilitates its tranſmiſſion. The periſtaltic action, by which it is urged through the inteſtine, is not a regular contraction proceeding from above downwards; but an undulatory or vermicular motion, commencing at once in ſeveral points, and deſtroying the inteſtinal curves in thoſe parts, by converting them into ſtraight lines. The portions immediately adjoining the contracted parts are dilated by the fluid impelled into them, and contract in their turn. The motion from above downwards prevails at laſt, ſo as to urge the reſidue of the chyme, from which the lacteals have extracted the chylous or nutritive parts, into the large inteſtine. The cauſe of the periſtaltic motion, which is obſerved in the muſcular fibres of the

inteſtine,

inteſtine, is the irritation of the aliment on the ſurface of the villous coat.

Nature and Properties of Chyle.

The difficulty of collecting a ſufficient quantity of this fluid from the lacteals, for the purpoſe of examination and analyſis, has left us in much ignorance concerning its nature. It ſeems to continue the ſame, in animals of the ſame ſpecies, notwithſtanding variations in their food. Yet it varies in the different claſſes of animals; being of a milky white in man and quadrupeds; tranſparent as water in birds and fiſhes; and ſome have deſcribed it as greeniſh in the herbivora. Other differences may perhaps exiſt in its properties in various genera; but, as far as our knowledge hitherto extends, it ſeems never to vary in man, however his food may be changed.

In ſpite of the importance of the reſearch, which we ſhould have expected to attract very early the notice of the philoſopher and chemiſt, our knowledge of the chyle is very limited, and its analyſis has hardly been attempted in a regular and ſcientific manner. Some deſcribe it as having the mild and ſlightly ſalt taſte of milk; as ſwimming in the ſerum of the blood, and poſſeſſing the lightneſs of oil; as uniting difficultly with water; as coagulating after death in its own veſſels, in the thoracic duct, or in parts where it has been effuſed. Others aſcribe to it a caſeous and a buttery matter; an abundance of earth; and ſome even admit a vegetable farina, combined with animal oil and lymph. It has alſo been repreſented as an oily matter, held in ſolution in water by means of a mucous principle. Dr. Fordyce's deſcription ſeems on the whole to be the moſt complete, and we ſhall therefore extract it from his "Treatiſe on Digeſtion."

"The chyle conſiſts of three parts; a part which is fluid and contained in the lacteals, but coagulates on extravaſation. Whether the veſſels act upon it ſo as to prevent it from coagulating; that is, ſo as to keep it diſſolved in water and fluid; or whether the fluid itſelf is alive, and coagulates by death, in conſequence of extravaſation, is an argument which I ſhall here not enter into. The ſecond part conſiſts of a fluid, which is coagulable by heat, and in all its properties reſembles the ſerum of the blood. (N. B. The chyle received into a veſſel ſeparates into theſe two parts; the coagulum is thick and firm and floats on the ſurface of the fluid portion. When an animal is killed, while the chyle is paſſing from the inteſtines into the lacteals, thoſe veſſels are found filled with a coagulated fluid; and in this way Mr. Cruikſhank has been enabled to repreſent them in his work on the abſorbents.) The third part conſiſts of globules, which render the whole white and opaque. Theſe globules have been ſuppoſed by many to be expreſſed oil; but this has not been proved. Neither has it been perfectly demonſtrated that ſugar is contained in the chyle, although it has been made very probable. The part coagulating on extravaſation, the part agreeing with ſerum in its qualities, and the globular part, which, in ſome animals, but not in quadrupeds, exiſts without giving whiteneſs to the chyle, alone, or along with ſugar, form the eſſential parts of the chyle.

"A great many ſubſtances may enter the lacteals along with the chyle; even ſolids reduced to fine powder. When indigo has been thrown into the inteſtine of a ſheep, I have ſeen the chyle rendered quite blue; now indigo is not ſoluble in water, but is a ſolid reduced into a very fine powder. So muſk gets into the chyle, giving it a ſtrong ſmell, and a great variety of other ſubſtances, of various colours, various taſtes, and various ſmells, each of them giving colour, or taſte, or ſmell to the chyle. Nevertheleſs, the lacteals ſeem to poſſeſs ſome power of rejection, ſince green vitriol, either exhibited along with the food, or thrown into the inteſtine after the animal has been opened, while the chyle was forming and abſorbing, gives no colour on infuſion of gall being applied to the chyle: nor if galls be thrown into the ſtomach along with the food; or if an infuſion of them be in like manner, thrown into the inteſtine, when an animal is opened during the time that the chyle is flowing into the lacteals, do they give any colour upon a ſolution of green vitriol being applied to the chyle; the galls might be ſuppoſed to be digeſted, but the green vitriol could not; neither can we well believe that the galls could be digeſted when thrown into a portion of the jejunum of about a foot in length tied at both ends.

"The lacteals, therefore, would ſeem to be ready to take in many things not digeſted, but not all. One would be diſpoſed to believe that what was injurious to the ſyſtem would be rejected by this power; yet when we conſider the great reaſon we have to believe that cantharides, mercury, and many other ſubſtances, are abſorbed by them, which certainly are in many caſes deleterious; we cannot well ground any doctrine on green vitriol and galls not being abſorbed.

"The ſubſtances which I have above pointed out to be the eſſential parts of the chyle, are totally different in all their properties from farinaceous matter, as well as the greateſt part of the other ſubſtances employed for food. A change conſequently of the properties of ſubſtances employed for food muſt take place in the organs of digeſtion, ſo as to convert the food into theſe different ſubſtances eſſentially contained in the chyle."

The ſame author obſerves again, "that the three parts conſtituting the chyle are exactly the ſame, whether the matter of a muſcular fibre, or farinaceous matter be digeſted; for I have fed a dog with farinaceous matter, and another with muſcular fibre, and opening them both during the time that the chyle flowed through the lacteals, collecting as much chyle as could be collected from each; on examination of their properties, they both conſiſted of the three eſſential parts I have already enumerated, each of theſe parts in the one was perfectly ſimilar, as far as I could contrive any experiment, to thoſe of the other."

"Moreover, in like manner, the properties of the part of the chyle ought to be different, when any one other of the ſeveral ſpecies of matter which may be employed for food is uſed; but that is by no means the caſe. The chyle of a cat, for inſtance, wholly living on animal food, is the ſame with, and cannot be diſtinguiſhed from, the chyle of an ox or ſheep, living wholly on graſs."

With all deference to the authority of the reſpected phyſiologiſt, whoſe words have juſt been quoted, we think ſome of his opinions not yet ſufficiently ſupported by obſervation and experiment; and we ſhall venture to ſubmit that the following queſtions are ſtill undecided, and form curious problems, towards the ſolution of which the united labours of the chemiſt and phyſiologiſt might be very advantageouſly directed. Does the nature of the food influence the character and properties of chyle? Does chyle receive an impreſſion from the properties of ſubſtances employed for food; and does it preſent, after its formation, any qualities analogous to thoſe of the alimentary matters? Are not the diſtinctive characters of chyle decided by the characteriſtic properties of foods?

In reſpect to the tranſmiſſion of colouring and odorous properties to the chyle, different ſtatements have been given by various phyſiologiſts. Some repreſent, with Fordyce, that indigo will turn it blue, that yolk of egg, or beet root, will

will make it yellow and red, &c. But, according to Fourcroy, (Syſt. de Conn. Chem. tom. 10. p. 66.) Hallé never found coloured matters affect the chyle in numerous experiments; and Dumas (Principes de Phyſiol. tom. 4. p. 406.) confirms this account by the reſult of his own experiments with various coloured and odorous ſubſtances.

Converſion of the Reſidue of the Food into Excrement.

The reſidue of the alimentary matter, conſiſting of the excrementitious part of the chyme with the oily, reſinous, and colouring portions of the bile, is tranſmitted by the periſtaltic action of the ſmall inteſtine, into the laſt diviſion of the digeſtive tube, the large inteſtine. Here it undergoes a further change, by which it is converted into a peculiar ſtate, denominated *fæces*. The large inteſtine, then, is the organ of this laſt change in the food, and it is further to be conſidered as a reſervoir deſigned to hold the excrement until it has accumulated to a certain quantity, and thereby to relieve us from the diſguſting neceſſity of its conſtant efflux. Here alſo abſorption of any nutritive parts that may have eſcaped the lacteals is carried on, but to a much ſmaller extent, as the diminiſhed number of abſorbent tubes ſufficiently teſtifies. That matters, however, are abſorbed, even from this portion of the canal, is abundantly evident from various conſiderations. The reſidue of the chyme is not more conſiſtent than a thick cream in the ileum; the greater firmneſs of the fœcal matter evinces the abſorption of the more fluid parts. Rhubarb injected in clyſters has imparted a yellow tint to the urine; and camphor, garlick, &c. have affected the pulmonary exhalation with their peculiar odours. Spirituous liquors and opium have alſo produced their effects on the conſtitution. Nutritive clyſters, conſiſting of milk, broth, &c. have, in various inſtances, ſupported life for ſeveral days, and even weeks. They have been retained in the rectum, and fœces have been expelled at certain intervals. In the caſe of ſtricture of the œſophagus, related in Dr. Currie's Medical Reports, life was ſupported in this way from October 18th, to December 6. The patient began with three clyſters a-day, each of which conſiſted of eight ounces of ſtrong broth, two yolks of egg, and forty drops of laudanum. As the retentive powers of the rectum improved, each clyſter was increaſed to ten ounces of broth, three yolks of egg, ſixty drops of laudanum, and eight ounces of wine. He had three or four ſolid, homogeneous ſtools of the accuſtomed fetor, but lighter than uſual in colour, in each week. His hunger was relieved by the injections. Are we to ſuppoſe that theſe never paſſed beyond the valvula coli; that the body could be nouriſhed for ſix or ſeven weeks by the abſorbents of the large inteſtine; and that this organ could make natural fœces from aliment which had never undergone the action of the ſtomach and ſmall inteſtine? Or ought we rather to ſuppoſe that the clyſters had entered the ſmall inteſtine? On the former ſuppoſition, we can eaſily explain why the body could not be nouriſhed for a longer time *per anum;* the comparatively ſmall number of abſorbents in the large inteſtine, and the want of the preliminary preparation of the aliment by means of the ſaliva, gaſtric juice, bile, pancreatic, and inteſtinal fluids, will ſufficiently account for the fact. At all events, we can only look to the employment of nutritive clyſters as a means of temporary ſupport; yet undoubtedly an efficacious and highly uſeful one for a ſhort time.

It has been generally repreſented by phyſiologiſts, that the fœces are the mere remains of the food undergoing certain changes of a putrefactive kind from their reſidence in the body. And the fœtor which they poſſeſs ſeems to have been the chief circumſtance leading to ſuch an opinion. We are, however, fully convinced that this ſentiment is erroneous, and that the converſion of the reſidual part of the chyme into fœces is no leſs a vital proceſs than the changes which the food experiences in the ſtomach or ſmall inteſtine; and that it will not admit of explanation on the ſuppoſition of ſpontaneous proceſſes, ſuch as putrefaction or fermentation, any more than digeſtion or chylification. The food or chyme expoſed out of the body to putrefaction would exhibit appearances altogether different from that homogeneous and ſolid texture which we ſee in healthy excrement. The diſengagement of ammonia, and the formation of various volatile products, would be the moſt ſtriking features of its decompoſition, neither of which take place in the body. Why ſhould fœces appear only in the large inteſtine, and never in the ſmall? And why ſhould the valve of the colon form ſo accurate a boundary between the reſidue of the chyme, a mild inodorous fluid, and the fœtid excrement, unleſs the properties of the latter were owing to the peculiar vital action of the large inteſtine? The fœcal vomitings attendant on ſome diſeaſes do not contradict this ſtatement, inaſmuch as they are partly explicable by the rejection of the yellow contents of the ſmall inteſtine, miſtaken for real excrement; and partly, if true fœces are actually thrown up, by an inverted periſtaltic action overcoming the reſiſtance of the valvula coli. So far from the fœces being the remains of the food in a putrid ſtate, we may affirm that they do not approximate to putridity in any character but the ſmell, which, too, is a peculiar and not a putrid odour. The vital changes which the aliments undergo, actually protects them from ſpontaneous degeneration, inſomuch, that in caſes of coſtiveneſs, the fœces remain unaltered in the inteſtines for weeks. If any chemical changes are obſerved in the digeſtive proceſs, they indicate an imperfect ſtate of that function, and they produce unuſual and unhealthy appearances in the evacuated matters, and ſympathetic diſturbances of the whole conſtitution. Natural excrement, indeed, is never voided, except when the vital changes operated in the ſtomach and ſmall inteſtine have preceded the vital action of the large inteſtine; and when the whole has been accompliſhed without any chemical change or ſpontaneous degeneration.

To the queſtion how theſe changes are produced, we ſhall not perhaps be able to give a very ſatisfactory reply. We have already noticed the abſorption carried on from the large inteſtine. There is alſo no doubt a ſecretion, particularly of mucous fluids from the ſurface, which may have ſome further effect than that of merely facilitating the progreſs of the inteſtinal contents. We are ignorant of the exact nature of thoſe in a ſtate of health; but we often find very copious morbid ſecretions evacuated *per anum* in diſeaſe. The appendix vermiformis has appeared to ſome perſons a chief agent in the proceſs of fœcification, not upon any ſufficient grounds, for it exiſts in very few animals, and it has been loſt in caſes of mortified hernia, in the human ſubject, without injury.

Air is diſengaged in ſmall quantities in the ſmall inteſtine, but ſtill more copiouſly in the large, which is frequently found diſtended from this cauſe, in the bodies of very healthy ſubjects. This may partly be atmoſpheric air ſwallowed with the food; but it conſiſts in a greater portion of other gaſes, as ſulphurated hydrogen.

Action of the large Inteſtine.

The contents of the large, as thoſe of the ſmall, are carried forwards by a ſpecies of periſtaltic motion. And this proceſs is partly owing to the alternate preſſure of the diaphragm and abdominal muſcles; partly to the action of the muſcular coat of the inteſtine. How eſſential the latter is, may be collected from the inability to void the fœces by the mere act of ſtraining, and from the evacuation being performed by

the inteſtine only in animals whoſe abdomen has been laid open, and in perſons who have taken purgative medicines. This irritability of the large inteſtine continues after apparent death, ſo as to produce even a degree of alvine evacuation.

The longitudinal muſcular fibres, being collected into ſtrong bands, and more numerous than in the ſmall inteſtine, act more powerfully. They are contracted towards the appendix vermiformis, in which they all terminate as in a common centre; they ſhorten and dilate the inteſtine, thereby render it fit to receive the alimentary reſidue from the ileum, and contribute to its progreſſion. The circular muſcular fibres, when diſtended by fœces or flatus, contract and propel it towards the rectum. The portion thus contracted is dilated by means of the longitudinal bands, and thus prepared for receiving new arrivals of fœcal matter. The periſtaltic action is perhaps moſt efficacious in the rectum, as that part has the ſtrongeſt muſcular covering. There is too in the large, as in the ſmall inteſtine, a retrograde or antiperiſtaltic effect, but it is weaker. It contributes to the longer retention, and more perfect elaboration of the fœces. The reality of this antiperiſtaltic motion is ſhewn by the vomiting of clyſters thrown into the rectum.

The fœces are gradually collected in the rectum, which admits readily of diſtenſion, for which it is particularly adapted by its nearly horizontal poſition, in the erect poſture of the body. They are retained for various ſpaces from twelve to twenty-four hours, until their weight, quantity, hardneſs, or acrimony, ſtimulate the inteſtine to action. The time of retention varies, even under circumſtances of health, according to the irritability, age, habits, &c. of the individual; according to the nature of the bile, the kind and quantity of the food, &c. If the ſubject be young, ſenſible, and irritable; the food containing much ſalt or ſpices, and abundant; the drink ſalt or ſtimulating; the bile fully formed; the excrement itſelf liquid; and the ſubject accuſtomed to evacuate it on the firſt call, ſtools will take place at ſhorter intervals. A coſtive ſtate of bowels will be found in aged, weak, and torpid ſubjects, in ſuch as take moderate quantities of mild and oily foods; where the bile is leſs in amount, and not fully developed in all its properties, and the excrement itſelf hard. Hence the bowels have been coſtive for weeks, and even months, but the perſons were indeed valetudinarians. The ingeſta paſs through the whole alimentary tube, in from ſix to twenty-four hours. If their retention exceeds the latter period, ſomething unnatural may be ſuſpected, although often they are evacuated at much longer intervals without any ill conſequences. Habit has much influence in this reſpect, both in determining the length of the interval, and the preciſe time of day at which the evacuation takes place.

Evacuation of the Fæces.

This is to a certain degree arbitrary in a healthy perſon, as it admits of being delayed for ſome time; but when the contractions of the rectum come on pretty ſtrongly, it is no longer in the power of the will to avoid the expulſion of the fœces. The act itſelf is preceded by a ſenſation of ſtimulus, and dull pain in the lower part of the belly, to which are added ſlight ſhiverings. This unpleaſant feeling excites us to employ that effort termed ſtraining (See RESPIRATION); and to exert the diaphragm and abdominal muſcles in combination, in order, by their preſſure on the rectum, to overcome the reſiſtance of the ſphincter ani, and expel the contents of the rectum. The levatores ani fix and ſupport the gut, and prevent it from yielding too much to this protruſive effort. When the anus is ſufficiently opened by means of this action of the reſpiratory muſcles, the rectum is emptied by its own living powers; by the irritability of its muſcular fibres. The ſtraining is therefore moderated, or entirely remitted, and the reſt of the expulſive act is accompliſhed without the aid of the will. When the large inteſtine is completely unloaded, the protruded rectum is reſtored to its ſituation, by the levatores ani, aſſiſted by the proper longitudinal fibres of the gut, and the anus is cloſed by means of its ſphincter. A ſenſe of pleaſure, not only in the part, but extending more or leſs over the whole body, accompanies the act.

Nature and Properties of the Fæces.

Some degree of variation in the conſiſtence of the fœces is compatible with a ſtate of health. They may be ſo firm as to have a conglomerated appearance, probably from being formed in the cells of the colon, or ſo much ſofter as not to preſerve this. Longer retention will contribute to that appearance, and the ſame circumſtance in exceſs cauſes a diſeaſed ſtate of the evacuations, in which they form hard balls called ſcybala.

Their colour depends on the admixture of bile; and muſt therefore vary according to the nature and properties of that fluid. In the moſt healthy ſtate it ſhould reſemble wetted rhubarb. Entire abſence of bile generally makes the fœces of a clayey appearance; and an altered biliary ſecretion will cauſe them to appear dark brown, green, black, &c., all which are morbid. Yet the colour is influenced, as well as the conſiſtence, by retention; becoming dark brown. The conſiſtence ſhould be homogeneous; and there ſhould not be any appearance of the food, as that indicates imperfect digeſtion. Yet ſome exceptions are made to this rule; ſpinach is ſaid to impart a green, and beet-root a red tint to the ſtools. The fibrous parts of animal and vegetable matter; huſks of grain, &c.; membranous parts, as ſkin of apples, grapes, &c. are often diſcerned. Traces of ſalted or ſmoked meats are diſcovered more frequently than thoſe of recent animal food. Haller ſtates their quantity at 5 oz. or rather more, when they are well formed; the quantity is greater when they are fluid. They are more fœtid and leſs in quantity from animal, than from vegetable ſubſtances, (being from 8 to 16 oz. in the latter caſe, according to Rye). Yet where milk alone, and bread and water are taken, the fœces poſſeſs a ſimilar odour to that of thoſe formed from meat or mixed diet. The taſte is ſaid to be ſweetiſh bitter and vapid, with ſometimes an acid admixture.

Chemical Analyſis.

In a recent ſtate they do not affect vegetable blue infuſions: loſe about three-fourths of their weight when dried upon a water bath. When diffuſed in water, and ſtrained through linen, a greyiſh brown matter remains; exhibiting, when dried, ſome vegetable remains, and amounting, in quantity, to $\frac{7}{100}$ of the whole. The ſtrained liquid depoſited, on ſtanding, a yellowiſh green ſlimy matter, ſeparable by the filter, and amounting to $\frac{14}{100}$. This was compoſed of a fatty matter, ſeparable by alcohol, and conſidered as the reſin of the bile a little altered: of a yellow ſubſtance diſſolved by water, and poſſeſſing the properties of gelatine or mucus: and of a greeniſh grey reſidue, inſoluble in water and alcohol, and leaving, when incinerated, ſome ſilica and phoſphate of potaſh. The liquid that paſſed the filter was at firſt yellow, then grew brown, and afterwards muddy: it contained albumen, bile, a peculiar reddiſh brown ſubſtance, ſuppoſed to be reſin of bile in an altered ſtate, and various ſalts.

The following is the result of the analyſis:

Water	73.3
Vegetable and animal remains	7.0
Bile	0.9
Albumen	0.9
Peculiar extractive matter	2.7
Salts	1.2
Slimy matter, conſiſting of reſin of bile, peculiar animal matter, and inſoluble reſidue	14.0
	100.0

The ſalts were carbonate of ſoda, muriate of ſoda, phoſphate of lime, ſulphate of ſoda, and ammoniaco-phoſphate of magneſia.

Having thus concluded our account of the digeſtive proceſs, we ſhall cloſe the preſent article with a ſingle remark, which flows naturally from the preceding ſtatements. The converſion of our food into the nutritive fluid by which the growth of our body is effected, and the loſſes of its organs are ſupplied, is an extremely complicated function, dependent on the right performance of ſeveral ſecretions, and the healthy action of various muſcular and irritable organs. The viſcera, in which theſe ſecretions are accompliſhed, are obnoxious to diſeaſe from many cauſes; the ſecretions themſelves, and the irritable action of the alimentary tube, although not influenced by the will, are obviouſly affected in a great degree by the ſtate of the brain and nerves. The digeſtive canal is expoſed to numerous ſources of indiſpoſition, from the improper nature and quantity of the food and drink, in which, from the artificial ſtate of ſociety, and the general prevalence of unnatural and luxurious habits, hardly any individual can be ſaid to purſue a ſtrictly healthy plan. When any one part of this ſeries of organs and functions is deranged from any of the cauſes now alluded to; when any diſeaſe of an idiopathic kind occurs in either of the long chain of parts immediately or remotely ſubſervient to the digeſtive proceſs; when diſorder ariſes from improper diet; or when it is more remotely induced by the influence of irritation or diſorder in the nervous ſyſtem, affecting the ſecretions and contractions on which the chylopoietic proceſs hinges: when, we repeat, any one part of the ſyſtem is thus diſturbed, derangement of the whole, from the mutual connection and dependency of all the parts, will be the probable reſult. As the chyle, the formation of which is the leading object of the whole digeſtive ſyſtem, cannot be rightly formed when that proceſs is diſturbed; and as this fluid is the great means of ſupport and repair to the body, the ſtate of our whole frame will be influenced by the diſturbance of the digeſtive organs; the nutritive fluid, not being duly prepared, will affect the nervous ſyſtem, and thereby again operate on the digeſtive organs. From the conſiderations now thrown out, it will be obvious that diſturbances of the digeſtive organs muſt be concerned, either as a cauſe or a conſequence of diſeaſe in a very large (probably much the largeſt) ſhare of diſorders that are preſented to the obſervation both of the phyſician and ſurgeon; and the important practical conſequences that may be drawn from theſe premiſes, are too obvious to eſcape the notice of the moſt ſuperficial. To follow their explanation any farther would be encroaching on the province of the pathologiſt and practitioner. Haller's Elementa Phyſiologiæ, tom. 6 & 7. Digestion *of Birds*, in *Comparative Anatomy*. See *Anatomy of* Birds.

Digestion, in *Chemiſtry*, is a long continued maceration of any ſubſtance in any ſolvent liquid, at a temperature kept ſteadily above the natural heat of the atmoſphere. It differs from ſimple maceration only in the temperature uſed.

Digestion, in *Surgery*, expreſſes a diſpoſition in abſceſſes to ripen and come to ſuppuration.

Tumours, ariſing on the parotides of children, are of eaſy digeſtion: they ripen in a little time. Dionis.

DIGESTIVE Faculty. The ancient philoſophers admitted a digeſtive faculty, or quality, in the human body; as not knowing how otherwiſe to account for the act of digeſtion. See Digestion.

Digestive is alſo uſed, in *Medicine*, for ſuch remedies as ſtrengthen and increaſe the tone of the ſtomach, and aſſiſt in the digeſtion of foods. To this claſs belong all ſtomachics and ſtrengtheners, or corroborants.

Digestive *Remedies*, in *Surgery*, are thoſe applications which the older ſurgeons conſidered as being efficacious to promote ſuppuration in wounds. (See Digestion and Suppuration.) Whatever has a tendency to excite the healthy action of the arteries in wounds, may produce a ſecretion of *pus*, and in this ſenſe, may not improperly be called a digeſtive remedy. All unguents, containing turpentine, roſin, aloes, and balſamic ſubſtances, poſſeſs this quality: but the common yellow baſilicum and tar-ointment are the moſt celebrated now in uſe. See Ointment.

Digestive *Salt*, in *Chemiſtry*, one of the names formerly given to muriat of potaſh.

DIGESTOR. A digeſtor is a thick iron boiler furniſhed with a ſtrong lid, which is made to ſcrew down perfectly tight, ſo as to confine all the ſteam or vapour from the incloſed liquid, and thereby enable it to acquire a degree of heat much higher than its natural boiling point.

This veſſel was at firſt contrived by Papin in the following way: A cylindrical veſſel is made, about a foot high, and ſix inches in diameter, of caſt-iron, or braſs, an inch thick, and turned very ſmooth on the inſide. At the upper end of the cylinder is a large opening of an oval form. A plate is then made of the ſame thickneſs as the cylinder, and of an oval form, like the aperture, but half an inch broader. To this plate is fixed a ſcrew, which paſſes through a thick piece of leather, with which the plate is covered. When the veſſel is filled with the ſubſtance intended to be heated, the plate is introduced into the cylinder (which the oval form of the aperture allows of) and is turned in ſuch a manner, that when it is pulled, the veſſel is cloſely ſhut up from the inſide. The projecting ſcrew is then thruſt through a hole made in the middle of a very ſtrong bolt attached to the veſſel, and, by means of the nut, the ſcrew is drawn ſo tight, as to preſs the cover ſtrongly up againſt the oval aperture, and thus to cloſe it perfectly.

Some alterations have been made in the conſtruction of the digeſtor, and mode of adapting the cover, and,

in particular, a ſafety-valve has been added, the ſtopper of which may be loaded by weights, or kept down by a lever, ſo that the degree of condenſation of the confined vapor (and, conſequently, the intenſity of heat within) may be regulated with tolerable accuracy.

The inventor, Papin, tried ſeveral curious experiments with this veſſel, particularly on the ſolvent power of water thus heated, far beyond its boiling point, over various animal and vegetable matters of difficult ſolubility. He found, that by this inſtrument, the firmeſt bones, when ground to powder, were rendered completely ſoluble in water, and cartilages with eaſe, and, in general, it may be obſerved, that almoſt all vegetable and animal matter may be thus diſſolved.

Digeſtors, or ſtrong iron boilers with a very cloſely-fitting lid, are often uſed in the making of ſoups, and other economical purpoſes.

DIGGES, Leonard, in *Biography*, who flouriſhed in the 16th century, was born at Digges Court, in the pariſh of Berham, in Kent. He finiſhed his education at Univerſity college, where he employed his time ſo well, that, in the world of buſineſs, he obtained the reputation of a ſkilful architect and ſurveyor, and a profound mathematician. He was alſo celebrated for his practical knowledge in fortification. As an author, he bore a reſpectable character: his works were, 1. "Tectonicum," which treats of menſuration and ſurveying: this was publiſhed in 1556 in quarto. 2. A geometrical treatiſe, entitled "Pantometria:" this was a poſthumous work, publiſhed by his ſon, who alſo gave the world an enlarged edition of the Tectonicum. 3. "A Diſcourſe on the Platonic Bodies:" and 4. A meteorological work, entitled, "Prognoſtication Everlaſting, of right good Effect, or Choice Rules to Judge of the Weather by the Sun, Moon, Stars, &c." This was re-publiſhed by his ſon, with corrections and conſiderable additions in 1592. He died about the year 1574, leaving behind him one ſon: viz.

Digges, Thomas, on whoſe education great pains were taken from his earlieſt years. At a proper time, he was ſent to Oxford, where he ſtudied with ſo much diligence and ſucceſs, that he became, in due time, one of the firſt mathematicians of the age. But his knowledge was not merely theoretical: when queen Elizabeth ſent aſſiſtance to the Netherlands, ſhe appointed Mr. Digges muſter-maſter-general; in performing the duties of this office, he not only acted the part of a faithful and excellent officer, but found means of perfecting himſelf in every department of military affairs. Beſides being the editor of his father's works, he wrote and publiſhed ſeveral books, which obtained for him a good reputation as a ſcholar and man of ſcience: but he was particularly eſteemed on account of his piety, which was equal to his learning. He died Aug. 24, 1595, and was buried in the church of St. Mary, Aldermanbury, where a monument was erected to his memory. He left behind him a ſon: viz.

Digges, Dudley, who was born in 1583, and in 1598 he was entered at Univerſity college, Oxford, where he very much improved himſelf in ſound learning, under the tuition of Dr. G. Abbot, who was afterwards archbiſhop of Canterbury. He took his degree of bachelor of arts in 1601, went and ſtudied in the inns of court; and thence he travelled on the continent for the improvement of his mind, and in order that he might attain a ſkill in foreign languages. In 1618, he was appointed ambaſſador to the czar of Muſcovy, and in two years afterwards he was joined in a commiſſion to Holland for obtaining reſtitution of ſome property ſeized from the Engliſh in the Eaſt Indies. He was elected member of parliament in 1621, and he was alſo member of the firſt parliament in the reign of Charles I. In 1626, he took an active part in the impeachment of Villiers, duke of Buckingham; and for a ſpeech which he delivered at a conference with the houſe of lords, he was committed to the Tower. The commons, however, vindicated his cauſe, and he was ſoon diſcharged from his confinement. In 1628, he was elected member of parliament for the county of Kent, and continued for ſome time to act with the patriotic party, but the temptation of a reverſionary grant of the office of maſter of the rolls was greater than he could withſtand. He accepted this in 1636, and from that time we hear nothing more of his public conduct. He enjoyed the emoluments of office but a ſhort time; having obtained them in 1636, and dying March 1639. As an author, this gentleman publiſhed in 1615 "A Defence of Trade; in a Letter to Sir Thomas Smith," and after his death was publiſhed in his name, "A Diſcourſe concerning the Rights and Privileges of the Subject." This was the ſubſtance of the ſpeech for which he was impriſoned. Some other of his ſpeeches may be found in parliamentary collections. He collected the letters which paſſed between the miniſters and others reſpecting the projected marriages between queen Elizabeth and the dukes of Anjou and Alençon, which were publiſhed in the year 1655, under the title of "The complete Ambaſſador, &c." In the former editions of the Biographia Britannica, the character of this gentleman has been too highly coloured, but the editor of the laſt edition has ſummed it up in few words, and to his deciſion we cheerfully aſſent: "He appears to have been a firm, but temperate oppoſer of the ſtretches of prerogative, by which the reign of king Charles I. was ſo unhappily diſtinguiſhed." This gentleman left a ſon, who proved himſelf a zealous friend of the court party, and wrote a work in 1643, to prove the unlawfulneſs of taking up arms by ſubjects againſt their ſovereign, in all caſes whatſoever, which has been frequently reprinted. Biog. Brit.

Digges, *Cape*, in *Geography*, a cape in the channel from Hudſon's ſtraits to Hudſon's bay. N. lat. 62° 45′. W. long. 79°.—Alſo, a cape in Baffin's bay, called cape Dudley. N. lat. 76° 48′. W. long. 59° 7′.

DIGGING, in *Agriculture*, the operation of breaking and turning up the ſoil by means of a ſpade. In caſes where labour is cheap, and a ſufficient number of hands readily provided, this would be an excellent method of preparing the ground for potatoe, carrot, and other root crops of a ſimilar kind, as the land would be looſened and broken up to a better depth than by the plough, and at the ſame time more effectually pulverized and reduced; in conſequence of which, weeds and graſs would be leſs apt to riſe, and injure the crops.

In this method, waſte lands may often be broken up and brought into tillage with great advantage and profit, in ſuch circumſtances as thoſe which have been mentioned. The increaſing price of farm-labour, however, operates greatly againſt the uſe of the ſpade in field-work.

Digging, in *Gardening*, the means of rendering garden ground in a proper ſtate for having different ſorts of crops ſown or ſet upon it. This ſort of work ſhould conſtantly be performed as nearly as poſſible to the time of putting in the ſeeds or plants, as in this ſtate a ſort of new fermentation takes place in the ſoil, by which heat is evolved, and other materials neceſſary for the growth of the crops formed and provided in it.

In caſes where the intention is chiefly that of bringing the ground into a ſuitable ſtate of reduction and mellowneſs of mould, it is only neceſſary to have the buſineſs of digging executed

executed in the autumnal or winter ſeaſons, being well ridged or laid up, ſo as to be fully expoſed to the action and influence of froſt and other cauſes, and be thereby brought into a proper condition for being levelled down and ſown or planted upon in the early ſpring months.

It is a beneficial practice in ſome caſes, in order to bring new land of this ſort into a ſuitable ſtate of preparation for the reception of crops, particularly where the under ſtratum or ſub-ſoil is of the more rich friable kind, to have it trenched over, paring off the ſurface, and turning it to the bottom, to be covered by the earth from below; but this ſhould never be attempted, except for tap-rooted plants, where the under ſoil is of a ſtiff unfriendly nature, as by ſuch means the bed for the immediate reception of the ſeeds or plants muſt become very unfit for their growth; while the more rich ſurface vegetable material, will be placed out of their reach and be loſt.

Work of this kind may be performed either in the autumnal or ſpring months, but the former is moſtly the better; in the more adheſive ſoils, however, it ſhould always be performed when the weather is dry, as under other circumſtances the mould is liable to become lumpy and uneven, and of courſe unfit for the putting in of crops.

In the performance of the firſt mode, or that of plain digging, the workman proceeds by beginning at one end of the piece of ground, forming a trench quite acroſs, to the depth of ſix or eight inches, or deeper where neceſſary, and the ſame width, conveying the earth taken out to the oppoſite end, where the digging is to finiſh; then proceeding with a ſecond courſe acroſs as before, turning the different ſpits of earth in a clean, neat, even manner into the former opening, continuing the ſame regular courſes, till the whole is dug over, breaking and reducing the lumps and clods as much as poſſible, being careful to preſerve a level even ſurface, having a proper regard to ſuch hollows as may be preſent. The earth taken out from the firſt opening or trench will ſerve to fill up and render the laſt even and level; and when dung is applied, it may either be ſpread evenly over the ſurface and be regularly turned in, or placed in the hollow or trench, and covered by the digging of the following trench. This is much the beſt practice where the dung is of the long or littery deſcription. As the buſineſs of digging proceeds the roots of different ſorts of perennial weeds, as twitch, bear-bind, and others of a ſimilar kind, ſhould all be carefully picked out, as they multiply exceedingly by being divided; and thoſe which are upon the ſurface of the ground be well turned to the botton of the former trench.

But in the latter, or trench method of digging, the uſual practice is to begin at one end of the piece of ground, and form or open by a line and the ſpade, a trench two ſpits wide, to the depth of one or two, removing the earth thus taken out to the contrary end, as noticed above, for the purpoſe of filling up the laſt trench; then to form a ſecond trench in the ſame manner after having pared off the ſurface, and placed it in the bottom of the former; proceeding in the ſame way till the whole is trenched over. In this mode it is the cuſtom to ſhovel up and take out the reduced mould or crumbs from the bottoms of the trenches in each courſe of digging. In executing the labour in this manner of digging, the workman ſtands with his ſide to the trench, while in the former caſe he faces it. This practice is particularly uſeful, where the ground is much infeſted with weeds, and where the ſoil is ſtiff, or not of great depth. The dung, in this method of digging, where it is performed to the depth only of one ſpit, may be depoſited in the bottom; but where two ſpades' depth are uſed, it ſhould be put in upon the firſt ſpit, after it has been dug off, and placed in the bottom of the former trench, as in this way it will not be buried to too great a depth, which, under other circumſtances, would be the caſe.

And the trench digging of garden ground may likewiſe be performed either in a level ſurface, as in the common manner of digging, or in the rough ridged mode: the former is the beſt method where immediate ſowing is intended; but the latter commonly where the land is to remain ſome time previous to its being cropped, as by this means it will derive the moſt advantage from the influence of the atmoſphere and the action of froſt, and be more fully reduced in its particles, ſo as to only require levelling down at the time of ſowing or putting in the crops. In caſes, however, where the ſoils are of a light thin gravelly, or ſandy quality, as they are apt to part with their moiſture too quickly, and do not ſtand much in need of pulverization, it would appear the beſt method to dig them conſtantly in the plain or level manner, as by ſuch means the effects of exhalation and the diſſipation of their moiſture may be the moſt effectually counteracted.

All ſorts of digging and levelling down of garden ground ſhould likewiſe, eſpecially in the ſtiffer ſorts of ſoil, be executed, when the land is in a condition ſomewhat inclining to dryneſs, as it can never be done to benefit when in a moiſt cloggy ſituation.

DIGGING. in *Mining*. See MINING.

DIGHTON, in *Geography*, a poſt-town of America, in the ſtate of the Maſſachuſetts and county of Briſtol; ſeven miles from Taunton, and 20 from Warren, in Rhode iſland. The townſhip contains 236 houſes, and 1666 inhabitants.

DIGIT, DIGITUS, in *Anatomy*. See FINGER.

DIGIT, in *Arithmetic*, ſignifies an integer, or number under ten; as 1, 2, 3, 4, 5, 6, 7, 8, 9.

DIGIT, in *Aſtronomy*, is the meaſure by which we eſtimate eclipſes: amounting to the twelfth part of the diameter of the luminary eclipſed.

The diameter of the body, or diſk, of the ſun or moon, is divided into twelve parts, called digits; and an eclipſe is ſaid to be of ten digits, when ten of thoſe parts are hid. Theſe digits, Wolfius, and ſome others, call digits eclipſed. When the luminary is juſt wholly covered, the digits eclipſed are preciſely 12; and when it is more than covered, which is frequently the caſe in lunar eclipſes, then more than 12 digits are ſaid to be eclipſed.

DIGIT is alſo a meaſure taken from the breadth of the finger. A digit is properly three-fourths of an inch, and equivalent to four grains of barley, laid breadth-wiſe, ſo as to touch each other.

DIGITALIS, in *Anatomy*, a term applied to the arteries and nerves of the fingers and toes.

DIGITALES *Volares Arteriæ*, are three branches ariſing from the arcus ſuperficialis volæ of the ulnar artery: ſee ARTERIES, *Deſcription of*.

DIGITALES *Pedis*, are three ſimilar arteries in the foot, given off from the arcus plantaris profundus. See ARTERIES.

DIGITALES *Nervi*, or the nerves of the fingers, are of two claſſes. The thumb, and each finger, has a large branch running along both its radial and ulnar ſide, towards the palmar ſurface, to the extremity of the organ. Theſe larger digital nerves are produced by the median and ulnar trunks, and accompany the digital arteries. The former of theſe trunks ſends two branches to the thumb, two to the fore, and two to the middle finger, and one to the radial ſide of the ring finger. The ulnar ſide of the latter finger, and both ſides of the ring finger, are ſupplied from the ulnar nerve. The dorſal ſurfaces of the fingers have a ſimilar ſup-

ply of two nerves each; but they are ſmaller. Thoſe of the thumb, fore, and middle fingers, and radial ſide of the ring finger, are ſupplied from the dorſal branch of the radial nerve; while the remainder are produced from the dorſal branch of the ulnar nerve.

In the foot the plantar digital nerves are derived from the two plantar branches of the poſterior tibial nerve; and the dorſal nerves from the ſuperficial peroneal nerves. See NERVES.

DIGITALIS, in *Botany*, (from *digitale*, the finger of a glove. The name appears firſt to have been given by the German writer Fuchs or Fuchſius, and hence the plant, being called *Digitalis Fuchſii*, ſeems to have acquired its Engliſh appellation, there being, as far as we can diſcover, no other name for it in our language.) Fox-glove. Fuchſ. Hiſt. 892. Linn. Gen. 313. Schreb. 410. Willd. Sp. Pl. v. 3. 283. Sm. Fl. Brit. 665. Juſſ. 120. Gærtn. t. 53. Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Luridæ*, Linn. *Scrophulariæ*, Juſſ.

Gen. Ch. *Cal.* Perianth in five deep, ovate or rounded, permanent ſegments; the upper one narroweſt. *Cor.* of one petal, bell-ſhaped; tube large, inflated, bellying beneath, contracted at the baſe; limb ſmall, unequally four-cleft, either obtuſely or acutely; the upper lobe often cloven, the lower largeſt. *Stam.* Filaments four, inſerted into the tube of the corolla, tapering at each end, bent, two of them longer than the others; anthers incumbent, in two diſtinct, pointed lobes. *Piſt.* Germen ſuperior, pointed; ſtyle ſimple, parallel with the ſtamens; ſtigma ſmall, acutely cloven. *Peric.* Capſule ovate, pointed, the length of the calyx, with two cells, and two valves, whoſe inflexed edges form the double partition, but the valves ſplit externally as well as at the ſummit. *Seeds* very numerous, ſmall, obovate, but ſomewhat angular, and rough.

Eſſ. Ch. Calyx in five deep ſegments. Corolla bell-ſhaped, five-cleft, inflated. Capſule ovate, of two cells with many ſeeds.

1. D. *purpurea*, Purple Britiſh Fox-glove, is the ſpecies beſt known. Linn. Sp. Pl. 866. Engl. Bot. t. 1297. Curt. Lond. faſc. 1. t. 48. Woodv. Med. Bot. t. 24. Fuchſ. Hiſt. 893. Ger. em. 790. "Segments of the calyx ovate, acute. Corolla obtuſe; its upper lip undivided. Leaves downy." It occurs in various parts of Europe on a dry chalky, loamy or gravelly ſoil, and is very abundant and magnificent about hills and the borders of fields or woods in the north of England, flowering in June and July. It is frequently kept for its beauty in gardens, and ſows itſelf plentifully, if the ſituation be dry, without requiring any care. The root is biennial. Stem erect, three or four feet high. Leaves large, ovate, crenate, downy. Flowers very numerous, in a long ſimple ſpike, large, crimſon, ſometimes white, elegantly ſprinkled with eye-like ſpots within. The whole herb when bruiſed has a bitter, nauſeous, and virulent flavour, and is one of the moſt dangerous of our native plants, acting violently on the ſtomach and bowels, and affecting the nerves by its narcotic powers. Hence it lowers the pulſe, affects the ſpirits in a moſt painful manner, and is ſtrongly diuretic. Some of the above qualities render it a valuable medicine, in careful hands, in dropſical, conſumptive, or epileptic caſes. It is ſaid to be uſeful as an external application to ſome ſorts of ulcers. 2. D. *minor*, a native of Spain, much reſembles the foregoing, but is ſmaller, with ſmooth leaves, and a more evident notch in the upper lobe of the flowers. 3. D. *Thapſi*. Linn. Sp. Pl. 284. Sm. Exot. Bot. t. 43. "Segments of the calyx oblong. Corolla obtuſe, its upper lip undivided. Leaves downy, decurrent." A native of Spain and Italy. This had been long loſt to our gardens, and was but little known to ſcientific botaniſts, till Mr. Lambert obtained it from Spain. It is a tolerably hardy perennial, and is cultivated with great ſucceſs at Kew. 4. D. *lutea*. Jacq. Hort. Vind. t. 105. "Segments of the calyx lanceolate. Corolla acute; its upper lip cloven." Grows in France and Italy, and has a long denſe ſpike of ſmall yellow flowers, and ſmooth leaves. It is a hardy perennial of no great beauty. 5. D. *ambigua*. Linn. Suppl. 282. (D. lutea; Fuchſ. Hiſt. 894. D. ochroleuca; Jacq. Auſtr. t. 57.) "Segments of the calyx lanceolate. Upper lip of the corolla emarginate. Leaves downy beneath." Found in Auſtria, Switzerland, and Germany. A very pretty perennial ſpecies, with elliptical denticulated leaves, and ſtraw-coloured flowers, beautifully ſpotted within. It ſeems to have been long overlooked or not well underſtood by Linnæus, who never ſaw it alive. The name given by Jacquin is preferable to that which has been retained.

There are ſeveral more of this genus, which reſemble each other in their narrow, ſmooth and rather rigid foliage; as D. *ferruginea*; D *obſcura*, Jacq. Hort. Vind. t. 91. D. *parviflora*; ibid. t. 17; D. *lanata*, Ehrh. Beitr. faſc. 7. 152, ſuppoſed to be a native of Hungary, and introduced by Dr. Smith to the Britiſh gardens in 1790; and another unſcientifically named *orientalis* (D. orientalis, tragopogi folio, flore albido, Tourn. Cor. 9,) which ought to have been called D. *ſpatulata*: it was found by Tournefort in Armenia, and is neareſt allied to the *lanata*.

Another tribe of ſpecies are natives of a warmer climate, and have tall ſhrubby ſtems, broader and ſerrated leaves, and handſome orange-coloured flowers; as D. *canarienſis*, Mill. Ic. t. 120; and D. *Sceptrum*, Sm. Exot. Bot. t. 73. Theſe are greenhouſe plants, and well worthy of cultivation. They are propagated by ſeeds, and require only to be kept from froſt, being natives of Madeira and the Canary iſlands.

Some other ſpecies of this fine genus are ſtill not at all or imperfectly deſcribed. A complete illuſtration of it, with coloured figures, has long been expected from the exquiſite pencil of Mr. Ferdinand Bauer, who in his travels to Greece, with Dr. Sibthorp, ſaw many of the plants wild, and attended to them with this object in view. They make a ſplendid part of the drawings deſtined for the *Flora Græca*. S.

DIGITALIS, in the *Materia Medica*. Though this valuable plant has ſtood on the liſt of the Materia Medica for ſeveral centuries, it may be ſaid to have been brought into notice, at leaſt among regular practitioners, almoſt entirely by the late Dr. Withering. This excellent phyſician was induced, in the year 1775, to make a trial of digitalis in the cure of dropſies, (in conſequence, indeed, of finding it mentioned in a popular recipe againſt this diſeaſe,) and the ſucceſs attending this practice was ſo marked, that after inveſtigating the properties of this plant for ten years, he gave the reſult of his experience in a very valuable treatiſe, publiſhed in 1786.

Since this period the ſingular properties of digitalis have been further inveſtigated by Darwin, Beddoes, Ferriar, Hamilton, and many other inquiring men, all of whom have entirely confirmed Dr. Withering's ſtatement in almoſt every particular; and in fact, though the uſe of this vegetable has been extended to many other diſeaſes, little has been added to the knowledge of its general properties ſince Dr. Withering's treatiſe.

Digitalis poſſeſſes two very ſtriking properties, which in no other ſubſtance are found combined, (at leaſt not in any conſiderable degree,) and to which are to be referred all the benefits derived from its uſe in various diſeaſes. One of theſe

theſe properties is a moſt ſurpriſing diminution in the ſtrength, and eſpecially in the frequency, of the pulſe, a diminution which extends not only to the reduction of an inordinate vaſcular action to the bounds of health, but even to bring it to a moſt unuſual and preternatural depreſſion; and if perſiſted in, finally to deſtroy life. Under the uſe of the digitalis, cautiouſly adminiſtered, a ſtrong pulſe of the uſual, or of increaſed quickneſs, will frequently ſink as low as forty beats in a minute, and ſometimes much leſs, without intermitting; and when once ſo reduced, the ſame effect may be ſteadily kept up for many days by a leſs doſe than that which at firſt reduced it. But if it be thrown into the conſtitution too ſuddenly, or if the quantity be too great, a moſt diſtreſſing and alarming anxiety at the heart, fainting, giddineſs, coldneſs of the extremities, pain of the head and temples, failure and irregularity of pulſe, inceſſant vomiting, and extreme debility will follow, and thus it may prove fatal.

The other effect of digitalis, is that of a very powerful diuretic; and it may be remarked that it ſeldom, if ever, acts in this manner, without a concomitant reduction of the frequency of the pulſe; and hence it is that the exhibition of this medicine, as a diuretic, requires ſo much caution, leſt the debility attendant on the ſudden diminution of the vaſcular action ſhould overſet a conſtitution already weakened and oppreſſed by dropſical effuſion.

In the uſe of digitalis, particular care muſt be taken not to increaſe the quantity or frequency of doſe too rapidly, as it often happens that no effect is produced for the firſt doſes; but when a conſiderable quantity has been taken, very violent ſymptoms are apt to follow ſo ſuddenly, as ſcarcely to allow time for any indication of the neceſſity of forbearance of this powerful medicine. This is particularly the caſe when the form of infuſion is adopted.

There are ſome conſtitutions, however, on which the digitalis, even in its moſt active ſtate, appears to have no manner of effect, whatever be the doſe, either on the pulſe, or the flow of urine, or on any other function of the body.

Conſiderable attention is required in the ſelection and preparation of the digitalis for medicinal uſe. Dr. Withering's uſeful directions, dictated by long experience, ought to be carefully adhered to. The leaves are to be gathered when the flower ſtems are ſhot up, but before the time of flowering; and the largeſt and deepeſt coloured leaves are preferable. Theſe are to be carefully dried in a warm room, through which a current of air is paſſing; and when completely criſp and dry, they are to be reduced to powder, and kept in bottles cloſely corked, and not expoſed to the light. In this ſtate the digitalis has a fragrant ſmell, not unlike new hay. The dried plant, well kept, will preſerve its virtues for a conſiderable time, but as an uniformity in ſtrength is always deſirable; and as all herbaceous plants gradually loſe their medicinal properties, it will be right for the apothecary to prepare it afreſh every year.

The digitalis is preſcribed in three different forms, in powder, in tincture, and in infuſion. The latter mode is preferable, when the full diuretic powers of the plant are wanted, as it acts with the moſt ſpeed and certainty. The infuſion recommended by Dr. Withering, and which is that commonly employed, is one drachm of the dried leaves, infuſed in eight ounces of boiling water to ſeven ounces, to which, when ſtrained, one ounce of any aromatic ſpirit is added. The firſt doſe of this infuſion to an adult, may be about half an ounce three times a day; and the quantity may be gradually increaſed by about a drachm daily, till the deſired effect follows, unleſs the reduction of the pulſe, and the other ſymptoms, ariſe to an alarming degree.

The powder may be given mixed with an aromatic, in doſes of about half a grain thrice a day, the quantity being gradually increaſed. When the digitalis is uſed for coughs and chronic complaints, where the ſedative power alone, and not the diuretic is wanted, the powder is often made into a pill, ſometimes combined with opium, or other remedies.

Dr. Ferriar has found the diuretic effect increaſed by combining it with calomel, and the pulvis ipecac. comp.; the doſe for an adult being half a grain of digitalis, a grain of calomel, and eight grains of the p. ipec. c. in two pills.

Dr. F. obſerves, that when the digitalis ſucceeds as a diuretic, it is generally in a few days; ſo that if it does not ſpeedily ſhew its effects, it is only a waſte of time to continue it longer.

The tincture of digitalis, recommended by Dr. Darwin, is made by digeſting two ounces of the dried leaves, coarſely powdered, in eight ounces of proof ſpirit for ſome days. The quantity of the plant here recommended is ſo great, as to ſoak up a great portion of the liquor, and ſtrong preſſure is required to obtain it ſeparate. The Edinburgh college uſe a tincture with only an ounce of digitalis to eight ounces of the ſpirit. The medium doſe of the ſtronger tincture to an adult, is at firſt no more than eight or ten drops; but it often muſt be increaſed to many times this quantity, before any ſenſible operation is produced.

In employing the digitalis, therefore, very accurate attention ſhould be paid to thoſe ſymptoms which we have already enumerated as following an exorbitant doſe; and eſpecially the ſtate of the pulſe ſhould be exactly noted as affording the ſafeſt guide to the practitioner. Where this medicine acts at all on the conſtitution, the pulſe is almoſt invariably reduced in frequency, ſo that the digitalis may be ſafely given in increaſing doſes till this effect is produced, after which point it will hardly be prudent to make a further increaſe, and the medicine muſt be diſcontinued as ſoon as the pulſe becomes irregular, intermitting, or when other marks of alarming debility come on. This, however, principally applies to the uſe of digitalis as a diuretic in the cure of dropſical effuſions of various kinds, where the full effect of this powerful plant is wanted; for in moſt other occaſions it will ſeldom be requiſite to puſh it ſo far.

We may juſt enumerate the diſeaſes for which this excellent medicine has been employed with advantage. In dropſy of every kind, except the encyſted, this medicine is often ſingularly uſeful; and when properly doſed, it evacuates the water with leſs diſturbance to the ſyſtem than any other diuretic. Like all other medicines of this claſs, however, it frequently fails to produce any effect without any obvious reaſon for ſuch failure, though not more frequently than any other medicine. In hydrothorax, either in its moſt decided form, or where the effuſion into any part of the cavity of the cheſt is only indicated by dyſpnæa, this medicine is often of ſingular utility, and under its operation the pulſe reſumes its regularity, and increaſes in ſtrength, unleſs the medicine be continued too long, or in too large a doſe.

In the above-mentioned diſeaſes, the benefit derived from the digitalis is chiefly owing to its diuretic powers, though not entirely ſo, ſince ſome advantage is attributable (eſpecially in effuſions into the cavity of the cheſt) to the diminution of the force of circulation.

There are many other caſes, however, in which the advantage derived from this medicine may be almoſt entirely referred to its power of reducing the force of the circulation. We have long wanted a remedy (as Dr. Ferriar juſtly obſerves) capable of lowering the pulſe, without increaſing evacuation to a dangerous degree. Hitherto we have only been able to effect it, either by withdrawing a quantity of the

the circulating fluids ſuddenly, or by producing nauſea. The digitalis is therefore an invaluable remedy in enabling the phyſician in moſt caſes to accompliſh this object; and this circumſtance has led to its employment in that moſt formidable and leaſt curable of all diſeaſes, pulmonary conſumption.

The ſucceſs which has attended this practice has been very various; many well marked and fully authenticated caſes have been recorded, in which all the ſymptoms that characterize inefficient pulmonary conſumption, pain of the ſide, frequent rigors, ſhort cough, bloody and puriform expectoration, a rapid pulſe, a parched ſkin, and great proſtration of ſtrength, have been entirely removed by digitalis given in doſes to affect the pulſe, and after the uſual antiphlogiſtic remedies, and the patients have entirely recovered. It appears, however, that though a conſiderable number of theſe caſes have received benefit from digitalis, yet, where the ſymptoms have ſo far advanced as to be unequivocal in their nature, the benefit has not been permanent; and, on the whole, it may be ſafely affirmed, that the chance of ſucceſs with this powerful medicine is much leſs in pulmonary inflammation and ſuppuration than in dropſical effuſions in any part of the body. There frequently occurs, however, in delicate, irritable habits, a ſlight hæmoptyſis, attended with cough, pain in the ſide, a quickened pulſe, and conſiderable debility, in which the ſymptoms are ſufficient to excite alarm for the ſafety of the lungs, though neither dyſpnæa nor purulent expectoration are preſent. In ſuch caſes bliſters and expectorants are uſually employed, and it is in theſe that the digitalis has been uſed with the happieſt effect, given in ſuch doſes as juſt to affect the pulſe and keep it within its natural ſtandard. The tincture is the preparation generally preferable in this caſe, as it is, on the whole, more manageable than the infuſion, and more certain than the powder.

Not only hæmoptyſis, but other hemorrhages are often relieved by digitalis, particularly menorrhagia, in which this medicine is peculiarly indicated, on account of the great debility occaſioned by the frequent recurrence of this diſtreſſing complaint, which forbids the uſe of an active antiphlogiſtic plan.

Digitalis has alſo been found of ſingular ſervice in ſpaſmodic aſthma, eſpecially when combined with opium, and in meaſles, particularly in the latter ſtages of this diſeaſe. Many other inſtances will occur to the judicious practitioner in which this ſingularly powerful medicine may be tried with rational hopes of ſucceſs.

DIGITALIS *Ferruginea*, in *Botany*. Dr. Plot, (Nat. Hiſt. of Staffordſhire, p. 196.) has deſcribed a foſſil remain of ſome kind, which preſents many, but not all, of the characteriſtic forms of the ſeed-veſſel of this ſpecies of plant: but the ſame ought, more properly, to be conſidered as an animal remain.

DIGITATUM FOLIUM. See LEAF.

DIGITUS, is the term uſually given to the fingers and toes. Digitus *index* is the fore-finger; *medius*, the middle finger; *annularis*, the ring-finger; and *minimus*, the little finger. The toes are generally deſignated by the names of digitus primus, ſecundus, &c. beginning with that which is next to the great toe.

DIGITUS *Veneris*, *Venus's finger*, in *Botany*, a name by which ſome authors have called the nymphæa, or water-lily.

DIGLIGGY-NEUR, in *Geography*, a town of Candy, in the iſland of Ceylon, next in importance to Candy, lies to the eaſtward of the capital about 10 or 12 miles, and in the direction of the Engliſh fort Batacolo. The diſtrict around it is more wild, barren, and impenetrable, than that which ſurrounds Candy; on this account it has been ſometimes choſen as a royal reſidence. At one period, when the king was driven out of Candy, and his capital burnt, he found here a retreat to which no European army has ever been able to penetrate. A few villages are ſcattered among the neighbouring hills; and in thoſe places where the woods have ſome clear ſpace, the ſoil, though very poor, produces rice.

DIGLITO, or DIGLATH, in *Ancient Geography*, a torrent of Aſia, whoſe ſource is in the fountain of the Tigris, in the eaſtern part of the mountains of Niphates; it runs from north-eaſt to ſouth-weſt, and diſcharges itſelf into the lake Arethuſa.

DIGLYPH, from δις, *twice*, and γλυφω, *I engrave*; a kind of imperfect triglyph, conſole, or the like, with only two channels, or engravings, inſtead of three. See TRIGLYPH.

DIGNAC, in *Geography*, a ſmall town of France, in the department of the Charente; nine miles S. of Angoulême.

DIGNANT, a town of Venetian Iſtria, about a league from the ſea. N. lat. 45° 10′. E. long. 13° 14′.

DIGNE, in Latin *Dinia*, or *Digna*, a ſmall but handſome town of France, in the deparment of the Lower Alps, chief place of a diſtrict, ſituated in a rich valley on the river Bléonne, which, not far from thence, falls into the Durance, 552 miles S. of Paris, and 42 S. by W. of Embrun. Lat. 44° 5′.

Digne is a very ancient town. Cæſar, in his Commentaries, calls it "Digna, inter montes poſita, &c." At the diſtance of one kiliometre is a mineral bath, celebrated for the wonderful cures which it performs in caſes of anchyloſis, or that ſtiffneſs which often takes place in a limb cured of a wound produced by a gun or piſtol-ſhot. All the ſprings in the neighbourhood of Digne are hot; the temperature of the water varies from 30 to 40 degrees of Réaumur's thermometer. It is taken externally and internally, but it has not yet undergone an exact chemical analyſis; it evidently contains much ſulphur and alkali, as it emits a very diſagreeable ſmell. Taken internally it operates as a ſtrong purgative. On the mountains from which the water iſſues the ſerpents have no venom, and children may play with them with impunity, whilſt thoſe which are found but at a ſmall diſtance from the ſprings, bite, and are venomous. Theſe mountains abound with curious petrifications; the crater, of an extinct volcano, is diſtinctly viſible on the top of one of the higheſt.

The town of Digne contains 2872, and the canton 10,362 inhabitants, diſperſed in 31 communes upon a territorial extent of 522½ kiliometres. As chief place of a diſtrict Digne

has a ſub-prefect, a court of juſtice, a regiſter office, a revenue inſpector, and a ranger. It is the ſee of a biſhop.

The diſtrict of Digne is compoſed of eight cantons, and has a population of 46,807 individuals, a territorial extent of 2480 kiliometres, and 88 communes. The ſoil produces corn and an abundance of excellent fruits, which are ſent to different parts of France, Italy, and Germany. There is much graſs-land and a great number of vineyards. The manufactures are thoſe of hardware, cutlery, houſehold furniture, and leather. The diſtrict contains likewiſe a mine of copper, in which gold and ſilver are frequently found: it is near Verdêche. In the neighbourhood of Mouſtiers a very fine clay is dug, of which they make excellent potter's ware. (Herbin Statiſtique de la France.)

DIGNITARY, in the *Canon Law*, a perſon who holds a dignity, that is, a benefice which gives him ſome pre-eminence in the choir above mere prieſts and canons Such is a dean and archdeacon, though the word is now abuſively applied to a mere prebendary or canon.

Dignities are ſometimes ſimple, ſometimes with cure of ſouls, and ſometimes with juriſdiction and adminiſtration of ſacred things. The canoniſts even define dignity, "adminiſtratio cum juriſdictione & poteſtate conjuncta." If the dignity have no contentious or exterior juriſdiction, it is a ſimple parſonage, and only gives pre-eminence. See Benefice, Parsonage, &c.

Of dignities, including prebends, Camden reckons in England 544 in number.

DIGNITY, a quality that denotes a man (*dignus*) worthy.

Dignity, in its moſt uſual acceptation, ſignifies honour and authority, reputation, &c.; and dignity may be divided into ſuperior and inferior; as the titles of duke, marquis, earl, viſcount, baron, &c. are the higheſt names of dignity; and, after the nobility, the firſt perſonal dignity is a knight of the garter; next after certain official dignities, as privy counſellors, the chancellors of the exchequer and duchy of Lancaſter, the chief juſtice of the king's-bench, the maſter of the rolls, and the other Engliſh judges, follow a knight banneret, baronets, knights of the bath, and knights bachelors. Theſe, ſays ſir Edward Coke, (2 Inſt. 667.) are all the names of dignity in this kingdom, eſquires and gentlemen being only names of worſhip. But before theſe laſt the heralds rank all colonels, ſerjeants at law, and doctors in the three learned profeſſions. See Precedence.

Nobility only can give ſo high a name of dignity as to ſupply the want of a ſurname in legal proceedings; and as the omiſſion of a name of dignity may be pleaded in abatement of a writ, &c. ſo it may be where a peer who has more than one name of dignity is not named by the moſt noble. 2 Hawk. P.C. 185. 230. No temporal dignity of any foreign nation can give a man a higher title than that of eſquire. 2 Inſt. 607.

DIGNITY, in *Oratory*, that part of elocution, which conſiſts in the right uſe of tropes and figures. It is not ſufficient for an orator to expreſs himſelf with propriety and clearneſs, or in ſmooth and harmonious periods; but his language muſt be ſuited to the nature and importance of the ſubject. As elegance gives rules for the firſt of theſe, and compoſition for the ſecond, dignity does the ſame for the laſt of them. This neceſſary variety of expreſſion ariſes, in a great meaſure, from tropes and figures, which not only enliven and beautify a diſcourſe, but likewiſe give it force and grandeur; for which reaſon this part of elocution ſeems to have been called *dignity*. See Figure and Trope.

DIGOIN, or Digouin, in *Geography*, a ſmall town of France, in the department of Saône and Loire, chief place of a canton, in the diſtrict of Charolles; 12 miles W. of Charolles, with a population of 2233 individuals. The canton has five communes, with 5352 inhabitants, upon a territorial extent of 90 kiliometres.

DIGOVILLE, a ſmall town of France, in the department of La Manche; 3 miles E. of Cherbourg.

DIGRESSION, in *Oratory*, is defined by Quintilian, agreeably to the etymology of the word, to be a going off from the ſubject we are upon to ſome different thing, which, however, may be of ſervice to it. Inſt. Or. lib. iv. cap. 3.

Digreſſion is not a neceſſary part of a diſcourſe, though it may ſometimes be convenient on ſeveral accounts; as where a ſubject is of itſelf flat and dry, and requires cloſe attention; in this caſe, it is of uſe to relieve the mind by ſomething agreeable and entertaining. But as it ſhould never be introduced without ſufficient reaſon, it ſhould never be too frequent, nor too long. Digreſſions in hiſtory, when rightly managed, afford the reader both delight and profit. Although they ſhould neither be too long nor too frequent; yet now and then to introduce a beautiful deſcription or ſome remarkable incident, which may give light to the ſubject, is ſo far from an interruption, that it is rather a relief to the reader, and excites him to go on with greater pleaſure and attention. Ward's Or. vol. i. p. 283, &c. vol. ii. 279.

DIGYNIA, in *Botany*, (from δι or δις, *double*, and γυνη, *a female*,) the name of ſuch Orders, in the principal Claſſes of the Linnæan artificial ſyſtem, as are characterized by two ſtyles in each flower, or, where the ſtyles are wanting, two ſeſſile ſtigmas. The principal of theſe Orders are the *Triandria Digynia*, and *Pentandria Digynia*, the former conſiſting entirely of the very natural order of true Graſſes, the latter of no leſs natural a tribe, the Umbelliferous plants, though theſe laſt do not occupy the whole artificial order. In the Claſſes *Icoſandria* and *Polyandria*, the ſtyles, if more than one, and leſs than ten, are very uncertain in number, ſo that it is found beſt in theſe inſtances to collect ſeveral Linnæan orders into one, they being, moreover, very ſmall. Some plants are called digynous, in Linnæan language, and others trigynous, though their ſtyle is ſimple, thoſe terms applying to their two or three ſtigmas, as in *Carex*, in which ſenſe, the great natural claſs *Syngeneſia* is likewiſe digynous. Some late writers on the genus *Carex* have undertaken to correct this trifling inaccuracy, by ſubſtituting the term *flores diſtigmatici*, which is certainly more correct, but far leſs commodious and conciſe. Such faſtidious accuracy applied to many graſſes would lead to more trouble than utility, for ſome have a ſtyle, or ſtyles, others none, which analogy and common ſenſe ſhew to be of no moment as to generical or claſſical diſtinction. S.

DIHELIOS, from δια, *through*, and ηλιος, *ſun*, in the *Elliptical Aſtronomy*, a name which Kepler gives to that ordinate of the ellipſis, which paſſes through the focus wherein the ſun is ſuppoſed to be placed.

DII, in *Ancient Geography*, a people of Thrace, placed by Thucydides in the province of Rhodope.

Dii *Adſcriptitii*, in *Mythology*, a claſs of deities of lower rank and dignity. See Dii *Indigetes*.

Dii *Averrunci* were, among the Greeks, the ſame with the alexicaci, or apopompæi, or apotropæi. Among the Egyptians theſe deities were repreſented in a menacing poſture, and ſometimes with whips in their hands. Of this kind was Iſis. Their buſineſs was to avert misfortunes. Apollo and Hercules belonged to this claſs of deities among the Greeks, and Caſtor and Pollux among the Romans.

Dii *Conſentes*, gods of the firſt rank and order. See Consentes.

Dii *Indigetes*. See Indigetes.

Dii *Manes*. See Manes.

Dii *Nixii*. See Nixii.

Dii *Olympii*, Olympian gods, the name given by the Athenians to the twelve chief deities, to whom they had dedicated a very magnificent altar.

Dii *Patrii*, among the Romans, were the three ſupreme deities, Jupiter, Juno, and Minerva. They were firſt received over all the Eaſt, and afterwards, ſucceſſively, in Greece and Italy. They are deſcribed as indigetes by Virgil, Georg. i. ver. 499, and as noſtri by Juvenal, Sat. iii. ver. 145.

DIJAMBUS, in *Poetry*, the foot of a Latin verſe of four ſyllables; it is compounded of two iambics, as *ſĕvērĭtās*.

DIJON, in *Geography*, an ancient and conſiderable town of France, in the department of the Côte d'Or, chief place of the department, and of a diſtrict of the ſame name, ſituated in an agreeable plain between the river Ouche on the ſouth, and a ſtreamlet, called Suſon, on the north, 228 miles S.E. of Paris, 60 N.E. of Autun, 63 W. of Beſançon, 138 N. of Lyons. It contains many remarkable ancient and modern buildings, ſeveral of which are of an aſtoniſhing elevation and boldneſs. St. Mary's, or the church of our lady (Notre Dame), is a Gothic edifice, of exquiſite taſte and uncommon lightneſs and delicacy. It was raiſed in the 13th century. The galleries have ſmall columns of two decimetres in diameter, and from five to ten metres high, all of a ſingle block. The arch is particularly admired, and the whole conſtitutes an unparalleled maſter-piece of architecture. The cathedral is equally remarkable for its grandeur and beauty. The ſpire is nearly 400 feet high. Behind the choir of this church is an ancient rotunda with three arches, one above the other, with a circular opening in the middle, and ſupported by 104 columns, the ſhaft of which is of a ſingle ſtone. A third of this edifice is buried under ground; it is the ruin of a Pagan temple.

Dijon is the native city of Boſſuet, Crebillon, and Piron. It is divided into three ſections, which form each a ſeparate canton, one of which compriſes 13 communes, and 11,864 inhabitants, the other 17 communes, and 12,175 inhabitants, and the third 14 communes, and 11,939 inhabitants. upon a territorial extent of 497½ kiliometres. The town itſelf has altogether a population of 21,000 individuals. Its principal manufactures are thoſe of woollen ſtuffs, hoſiery, play-cards, leather, wax-candles, muſtard, ſweet-meats, and a cotton ſpinnery.

As chief place of the department and of a diſtrict, Dijon has a prefect, four courts of juſtice, and a regiſter office. It is the ſee of a biſhop.

The principal trade of the diſtrict is with corn and cattle, but chiefly with wine, which is ſent to Paris, Straſbourg, Holland, and Switzerland. The produce of a French arpent in wine averages in this diſtrict a net profit of 89 French livres. It yields Burgundy of the very firſt quality.

The population of the diſtrict of Dijon amounts to 122,532 individuals, diſperſed in 14 cantons, and 270 communes, upon a territorial extent of 3112½ kiliometres. N. lat. 47° 19′. E. long. 4° 57′. Herbin Statiſtique de la France.

By obſervations of four years, ending in 1781, the temperature of this town is 52°·8′. The ſtandard temperature is 55.°3; the difference 2.5; but the diſtance of Dijon, from the ſtandard, is 260 miles, which gives a diminution of 1.7 degrees. It is cooled ſomewhat farther, by a ridge of mountains to the weſt of it, and the chain of Jura, about 60 miles to the eaſt. Kirwan's Eſtimate of the Temperature of Places, &c. p. 80.

Dijon was founded by the emperor Aurelian, when he viſited Gaul, which, in its origin, was a caſtle, and not a city.

DIIPOLIA, Διιπολεια, in *Antiquity*, an Athenian feſtival, celebrated in honour of Jupiter Polieus, or protector of the city. For the ceremonies obſerved at this ſolemnity, ſee Potter's Archæol. Græc. lib. ii. c. 20. tom. i. p. 381.

DIKE, in *Agriculture*, a name frequently applied to a ditch. It likewiſe ſignifies a dam, or mound of earth, raiſed to prevent inundations; and ſometimes even a water-ditch uſed as a diviſion-fence.

The word ſeems formed from the verb, *to dig*; though others chooſe to derive it from the Dutch, *diik*, a dam, ſea-bank, or wall.

Dike, or *Dyke*, alſo denotes a work of ſtone, timber, or faſcines, raiſed to oppoſe the entrance or paſſage of the waters of the ſea, a river, lake, or the like.

The word comes from the Flemiſh, *dyk*, or *diik*, a heap of earth to bound or ſtem the water. Junius and Menage take the Flemiſh to have borrowed their word from the Greek τειχος, *wall*. Guichard derives it from the Hebrew *daghah*.

Theſe dikes are uſually elevations of earth, with hurdles or ſtakes, ſtones, and other matters.

The dike of Rochelle is made with veſſels faſtened to the bottom. The dikes of Holland are frequently broke through, and large tracts of land are then drowned.

DIKOWO, in *Geography*, a town of Bohemia, in the circle of Konigingratz; nine miles E. S. E. of Gitſchin.

DILAPIDATION, a waſteful deſtroying, or letting buildings, eſpecially parſonage houſes, run to ruin and decay, for want of neceſſary reparation.

An action lies for dilapidations, either in the ſpiritual court by the canon law, or in the courts of common law; and it may be brought by the ſucceſſor againſt the predeceſſor, if living, or, if dead, againſt his executors.

It is ſaid to be good cauſe of deprivation, if the biſhop, parſon, vicar, or other eccleſiaſtical perſon, dilapidates the buildings or cuts down timber, growing in the patrimony of the church, unleſs for neceſſary repairs. (1 Roll. Rep. 86. 11 Rep. 98. Godb. 259.) And that a writ of prohibition will lie againſt him in the courts of common law. (3 Bulſtr. 158. 1 Roll. Rep. 335.) By ſtatute 13 Eliz. c. 10. if any ſpiritual perſon makes over or alienates his goods, with intent to defeat his ſucceſſors of their remedy for dilapidations, the ſucceſſor ſhall have ſuch remedy againſt the alienee, in the eccleſiaſtical court, as if he was the executor of his predeceſſor. And alſo money recovered for dilapidation, muſt be employed, by 14 Eliz. c. 11. in the repair of the ſame houſes, within two years, on penalty of forfeiting double the value to the crown.

DILATATION, (from the Latin *dilatatio*,) is the enlargement of bodies after a ſtate of compreſſion, or in conſequence of the introduction of other ſubſtances amongſt their component particles; thus, when part of the air is drawn out of the receiver of an air-pump, the remaining air becomes dilated; thus alſo wood, paper, &c. are dilated by moiſture; and all bodies are dilated by heat. See Elasticity, and Expansion.

Dilatation, in *Surgery*, denotes the laying open any orifice, or the lips of a wound wider, or the extenſion of any veſſel, or the like.

This is done by an inſtrument called a dilatatorium.

DILATED Vein, in *Mining*, called alſo a *flat vein*, or *ſtreak*, denotes ſuch a depoſitory of ore as lies between ſtrata, like ſeams of coal, and commonly occurs in argillaceous

ſtrata; it differs from a pipe-vein, in conforming to the lamina of the ſtrata inſtead of occupying an irregular cavity, approaching to an horizontal poſition.

DILATATOR *alæ naſi*, in *Anatomy*, is the name by which Cowper has deſcribed that portion of the levator labii ſuperioris et alæ naſi, which is inſerted in the cartilaginous ala of the noſe. See the deſcription of that muſcle in the article DEGLUTITION.

DILATATOR *pinnarum proprius*, is a name given by Santorini to the depreſſor alæ naſi.

DILATATOR *urethræ*, is the accelerator muſcle, which ſee.

DILATATOR *urethræ poſticus*, is a faſciculus of fibres running forwards in the perineum, from the ſphincter ani to the accelerator urinæ, and deſcribed by Heiſter as a diſtinct muſcle.

DILATORY PLEAS, in *Law*, are ſuch as are put in merely to delay the ſuit, by queſtioning the propriety of the remedy, rather than by denying the injury; whereas, pleas *to the action* are ſuch as diſpute the very cauſe of ſuit.

The former cannot be pleaded after a general imparlance, which is an acknowledgment of the propriety of the action. (See IMPARLANCE). Dilatory pleas are, 1. To the juriſdiction of the court; alleging, that it ought not to hold plea of this injury, it ariſing in Wales or beyond ſea; or becauſe the land in queſtion is of ancient demeſne, and ought only to be demanded in the lord's court, &c. 2. To the diſability of the plaintiff, by reaſon of which he is incapable of commencing or continuing the ſuit; as, that he is an alien enemy, outlawed, excommunicated, attainted of treaſon, or felony, under a præmunire, not in *rerum natura* (being only a fictitious perſon), an infant, a feme-covert, or a monk profeſſed. 3. In abatement (which ſee). Theſe ſeveral pleas were formerly very often uſed as mere dilatory pleas, without any foundation of truth, and calculated only for delay; but now by ſtatute 4 and 5 Ann. c. 16. no dilatory plea is to be admitted without affidavit made of the truth thereof, or ſome probable matter ſhewn to the court to induce a belief of its truth. And with reſpect to the pleas themſelves, it is a rule, that no exception ſhall be admitted againſt a declaration or writ, unleſs the defendant will, in the ſame plea, give the plaintiff a better, (Brownl. 139.); that is, ſhew him how it might be amended, that there may not be two objections upon the ſame account. Nor thus, by ſtatute 8 and 9 W. III. c. 31. ſhall any plea in abatement be admitted in any ſuit for partition of lands, nor ſhall the ſame be abated by reaſon of the death of any tenant. When theſe dilatory pleas are allowed, the cauſe is either diſmiſſed from that juriſdiction, or the plaintiff is ſtayed till his diſability be removed, or he is obliged to ſue out a new writ, by leave obtained from the court, (Co. Entr. 271.), or to amend and new-frame his declaration. But when, on the other hand, they are over-ruled as frivolous, the defendant has judgment of *reſpondeat ouſter*, or to anſwer over in ſome better manner. It is then incumbent on him to plead.

DILATRIS, in *Botany*. (ſo called by Bergius, from δις, *double*, and λατρις, a *ſervant* or *attendant*, as it ſhould ſeem, becauſe he found two of the anthers ſmaller than the third, and therefore he preſumed them to be inefficient, and merely an accompaniment to that. We find them, as Linnæus did, all perfect. See *Exot. Bot.*) Berg. Pl. Cap. 9. Linn. Suppl. 10. Schreb. 37. Willd. Sp. Pl. v. 1. 246. Juſſ. 59. Lamarck, t. 34. Claſs and order, *Triandria Monogynia*. Nat. Ord. *Enſatæ*, Linn. *Irides*, Juſſ.

Gen. Ch. *Cal.* none. *Cor.* Petals 6, ſuperior, ovato-lanceolate, or linear, concave, ſlightly ſpreading, equal, hairy externally, permanent. *Stam.* Filaments three, awl-ſhaped, longer than the petals, one of them ſmaller than the reſt: anthers ovato-lanceolate, with two furrows, all (as far as we can find) equal in ſize. *Piſt.* Germen inferior; ſtyle thread-ſhaped, as long as the ſmaller ſtamen; ſtigma ſimple, acute. *Peric.* Capſule globoſe, very hairy, of three cells and three valves. *Seeds* ſolitary, orbicular, compreſſed, ſmooth, vertical.

Eſſ. Ch. Calyx none. Petals ſix, regular, hairy. One ſtamen ſmaller than the other two. Stigma ſimple. Capſule inferior, of three cells and three valves. Seeds ſolitary, round, compreſſed.

1. D. *corymboſa*. Berg. Pl. Cap. 9. t. 3. f. 5. Thunb. Prod. 10. Willd. Sp. Pl. v. 1. 246. Sm. Exot. Bot. v. 1. 29. t. 16. (D. umbellata; Linn. Suppl. 101. Mart. Mill. Dict. Wachendorfia umbellata; Linn. Syſt. Veg. ed. 13. 80. Ixia hirſuta; Linn. Mant. 27. 320. 511.) Broad-petalled Dilatris. "Petals ovate. Flowers in a flattiſh hairy tuft." A native of the Cape of Good Hope, probably in a ſandy ſoil. It flowered in Meſſrs. Lee and Kennedy's hot-houſe at Hammerſmith. Root perennial, with woolly fibres. Stem ſimple, a foot high, round, downy. Leaves moſtly radical, ſheathing, two-ranked, ſword-ſhaped, ſmooth, rather glaucous, orange at their baſe. Flowers numerous, pale lilac. Stalks red, hairy. 2. D. *viſcoſa*. Linn. Suppl. 101. Thunb. Prod. 10. Willd. Sp. Pl. v. 1. 247. Mart. Mill. Dict. Narrow-petalled Dilatris. "Petals linear. Flowers in a viſcid hairy tuft." Gathered by Thunberg on the top of Table Mountain, Cape of Good Hope. It is larger than the preceding, with broader leaves, the ſtem and inflorescence more hairy and viſcid. Petals very narrow, and extremely hairy. This is the ſpecies figured by Lamarck in his plate above quoted. 3. D. *paniculata*. Linn. Suppl. 101. Thunb. Prod. 10. Willd. Sp. Pl. v. 1. 247. Mart. Mill. Dict. Lanceolate-petalled Dilatris. "Petals lanceolate. Panicle oblong." Gathered likewiſe by Thunberg at the Cape. It is, as far as we know, a ſtranger in our gardens, like the laſt. Its flowers are ſaid to be purpliſh, with a yellow tinge, and the panicle is elongated and viſcid.

DILE, in *Botany*, a name by which ſome authors have called the iſatis or woad. Ger. Emac. Ind. 2.

DILEMMA, Διλημμα, in *Logic*, an argument conſiſting of two, or more propoſitions, ſo diſpoſed, that grant which you will of them, you will be preſſed by the concluſion.

The word is formed from the Greek δις, *bis*, *twice*, and λημμα, *ſumptio*.

A dilemma is an argument conſiſting of two contrary parts, or ſides, either of which catches the adverſary. And hence it is alſo called ſyllogiſmus cornutus, a horned ſyllogiſm, its horns being ſo diſpoſed, that if you avoid the one, you run upon the other.

It is alſo called crocodilinus, by reaſon that as the crocodile leads ſuch as follow it, into the water, and purſues ſuch as fly it, to deſtroy them; ſo, whatever the adverſary either affirms, or denies, in this kind of ſyllogiſm, is turned to his diſadvantage.

For an example: A philoſopher once diſſuaded a man from marrying, by this argument: Either the woman you marry will be handſome, or ugly; if handſome, ſhe will give you jealouſy; if ugly, diſpleaſure.

Cicero uſes this fine dilemma, to prove, that all pain is to be borne with patience: "Omnis dolor aut eſt vehemens, aut levis; ſi levis, facile feretur; ſi vehemens, certe brevis futurus eſt."

The ſame orator, by another dilemma, proves that no meſſengers ſhall be ſent to Antony: "Legatos decernitis; ſi ut deprecentur, contemnet: ſi ut imperetis, non audiet."

Nor

Nor muſt we here omit that beautiful dilemma of Tertullian, whereby he clears the Chriſtians, and accuſes Trajan, who had forbad the ſeeking them out, and yet ordered them to be puniſhed when found: "O ſententiam neceſſitate confuſam! negat inquirendos, ut innocentes; et mandat puniendos, ut nocentes: parcit et ſævit, diſſimulat et animadvertit! quid temetipſum cenſura circumvenis? ſi damnas, cur non et inquiris? ſi non inquiris, cur non et abſolvis?"

For a dilemma to be legitimate, there are two things required: 1. A full enumeration of parts; thus that of Ariſtippus above-mentioned, whereby he diſſuades from marriage, is invalid, as being defective in the enumeration; there being a middle degree, or form, between handſome and ugly.

2. That the dilemma preſs the adverſary alone, and that the perſon who makes it be not liable to have it retorted upon him. This was the caſe in that celebrated dilemma of the ſophiſt Protagoras, which the Areopagites, with all their wiſdom, were not able to reſolve.

A youth named Euathlus, engaged with Protagoras, to learn dialectics, upon condition, that he ſhould pay him a large ſum of money, the firſt cauſe he pleaded, in caſe he gained the ſame. Euathlus, when fully inſtructed, refuſing to pay the promiſed reward, Protagoras brings his action, arguing thus: You muſt pay the money, however the cauſe terminate; for if I gain, you muſt pay me in conſequence of the ſentence, as being caſt in the cauſe; and if you gain it, you muſt pay in purſuance of our covenant, and, therefore, whether the cauſe goes for me, or againſt me, you muſt pay me the reward. Nay, retorts Euathlus, which way ſoever the cauſe go, you will have nothing: for if I prevail, the ſentence gives it that nothing is due to you; and if I loſe, then there is nothing due by the covenant; and therefore, whether I gain or loſe the cauſe, I will not pay you; for nothing will be due to you. It is ſaid, that the court, unable to decide in favour of either party, ordered them both to appear in court again an hundred years afterwards, to receive judgment.

After the like manner, an ancient prieſteſs diſſuading her ſon from haranguing the people, by this dilemma, "nam ſi injuſta ſuaſeris," ſays ſhe, "habebis Deos iratos: ſin vero juſta, iratos habebis homines:" the youth thus returned the dilemma on his mother: "imo," ſays he, "expedit ad populum verba facere, nam ſi juſta dixero, Dii me amabunt; ſi injuſta, homines."

DILEN, in *Geography*, a river of Hindooſtan, which riſes beyond, that is, to the north or north-weſt of Ghizni, and receives near Gardaiz another river named Semil; after which the confluent river takes the name of *Cow*, and purſuing its courſe towards Nughz, receives near that place another river, which comes from the quarter of Candahar. See Cow.

DILETTANTE, Ital.; equivalent with *amateur*, Fr. The word is formed, in modern times, from *dilettare* of *dilettator*, Lat.; one who gives and receives delight from the ſucceſſion and combination of ſounds in muſic.

An Italian dilettante is one delighting in muſic, who has made a conſiderable progreſs in the art, not as a profeſſor, but merely for his own amuſement and that of his friends. See Amateur.

DILICTUM, a term uſed, by Agricola, to expreſs a brine, made by pouring water upon ſand, ſtones, earth, &c. that had been before ſtrongly impregnated with ſea-ſalt; from this brine, a ſalt, for the uſe of the table, was made by evaporation in his time, and is ſtill ſo in many parts of the world. At Junthall, in Germany, they have a ſalt work of this kind, where they make at the rate of eight hundred loaves of ſalt in a week, each loaf weighing four hundred weight.

DILIGENCE, in *Ethics*, a virtue which conſiſts in the active and continued exerciſe of the faculties, and uſe of means for the attainment of any object, whatever that object may be.

Diligence, in *Scots Law*, ſignifies either that attention and care which perſons are bound to exerciſe in the conduct of certain contracts or truſts, and which varies according to the nature of the contract; or, it denotes certain forms of law by which a creditor endeavours to make good his payment, either by affecting the perſon of his debtor, or by ſecuring the ſubjects belonging to him from alienation, or by carrying the property of theſe ſubjects to himſelf.

They are either real or perſonal. Real diligence is that which is proper to heritable or real rights: and perſonal is that by which the perſon of the debtor may be ſecured, or his perſonal eſtate affected. Of the firſt ſort we have two, viz. *inhibition* and *adjudication*, which ſee reſpectively. The latter diligences are *arreſtment* and *poinding*, which ſee.

DILIGENZA, in the *Italian Muſic*, is uſed for a ſoft or ſweet manner of ſinging or playing.

DILIMNITÆ, in *Ancient Geography*, one of the moſt conſiderable of thoſe nations which inhabited Perſia, on this ſide of the Tigris.

DILIN, in *Geography*, a town of Hungary; two miles north of Schemnitz.

DILIS, in *Ancient Geography*, *Lauron*, a port on the coaſt of Gallia Narbonnenſis, eight miles weſt from Incarus, according to the Itinerary of Antonine. M. d'Anville ſays that it is the port of Pontheu, which is eight miles from Carri.

DILL, in *Botany*. See Anethum.

Dill, in *Agriculture*, a name applied to a plant frequently cultivated as a field crop in Glouceſterſhire, and which Mr. Rudge, in his ſurvey of that diſtrict, ſuppoſes to be the *Anethum ſegetum* of Linnæus, and a native of Portugal: but on the Cotſwould hills the ſame term is often given to a large ſort of vetch, which has been there grown for hay for a great length of time.

It is found, according to the writer juſt mentioned, to afford an excellent hay for all ſorts of cattle, but particularly for ewes with ſucking lambs, producing an abundance of highly nutritious milk; and it has the very excellent property of thriving well on ſoils of the poor, thin, and impoveriſhed kind, where other ſorts of artificial graſs-ſeeds would afford but a ſcanty return. In colour the ſeeds incline to red, reſembling thoſe of the vetch in ſhape, but ſmaller.

It is uſual to ſow them broadcaſt in March or the following month, in the proportion of about a buſhel and a half to the acre. They ſoon cover the ground, and require no hoeing or other attention till they are ready for cutting, which, in the moſt favourable ſeaſons, is ſeldom the caſe before the middle or latter end of September, when left for ſeed.

Some cultivators are, however, found to cut it for hay before the bloſſom withers, and then it produces about a ton on the acre: but this is conſidered as the leaſt beneficial mode, as the ſtraw, after the ſeed has been threſhed out, is but little, if at all, inferior to the early mowed. The kid, or pod, has the reſemblance of a pea, and ſhould always be fully ripe before it is harveſted, though, when in too great a ſtate of maturity, it is apt to ſhed on being moved.

The quantity of ſeed which is afforded per acre is frequently ſo much as twenty-four buſhels; the price varying from five ſhillings to eight ſhillings the buſhel.

When ground with barley it has been found to be excellent food for fattening cattle and hogs.

It

It is, perhaps, a ſort of crop that may be grown with advantage on the inferior ſorts of ſoil in moiſt ſituations.

DILL, in *Geography*, a town of Germany, in the circle of the Upper Rhine, and ſeat of a juriſdiction in the county of Spanheim; 26 miles W.N.W. of Creutznach.

DILLA, a mountain and promontory of India, on the coaſt of Malabar, ſituated in N. lat. 12° 1′. E. long. 75° 2′, or 1° weſt of Cochin.

DILLENBURG, a ſmall town of Germany, in the circle of Weſtphalia, on the river Dill; 27 miles N.W. of Marpurg; 54 N. of Francfort on the Mayn; and 60 E. of Bonn. Lat. 50° 45′. It has an ancient caſtle, and belonged to the princes of Naſſau Dillenburg; but it is now in the conſcription of the new kingdom of Weſtphalia. See NASSAU.

DILLENIA, in *Botany*, a magnificent Eaſt Indian genus of plants, named by Linnæus in honour of John James Dillenius, the firſt Sherardian Profeſſor at Oxford; "becauſe," as he himſelf informs us in his Critica Botanica, p. 80. "it is of all plants the moſt diſtinguiſhed for the beauty of its flower and fruit, like Dillenius among botaniſts." Linn. Gen. 277. Schreb. 372. Willd. Sp. Pl. v. 1. 1251. Juſſ. 281. Claſs and order, *Polyandria Polygynia*. Nat. Ord. *Magnoliæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five roundiſh, concave, large, coriaceous, permanent leaves; at length becoming pulpy, enveloping the capſule. *Cor.* Petals five, roundiſh, concave, large, ſomewhat coriaceous. *Stam.* Filaments very numerous, linear, crowded, ſhorter than the petals, permanent; anthers terminal, erect, oblong, with a recurved point. *Piſt.* Germen ſuperior, roundiſh, depreſſed, aggregate, of about 20 cells; ſtyles none; ſtigmas one to each cell, oblong, depreſſed, ſpreading in the form of a ſtar. *Peric.* Capſules about 20, juicy when ripe, compreſſed, ranged circularly round a pulpy receptacle, and covered by the pulpy permanent calyx. *Seeds* ſeveral in each capſule, inſerted along its inner edge, compreſſed, fringed at their outer margin.

Eſſ. Ch. Calyx inferior, of five coriaceous permanent leaves. Petals five. Capſules ſeveral, compreſſed, many-ſeeded, ranged circularly round a pulpy receptacle.

Linnæus derived his characters of this genus from the deſcription and figures in the *Hortus Malabaricus*, v. 3. t. 38, 39, with the inſpection of a dried ſpecimen only. Hence he has not well characterized the ſeeds as "imbedded in pulp *under* the capſules." The fruit was firſt explained more correctly in Dr. Smith's Exotic Botany, v. 1, where, however, in the full deſcription, the capſule is ſaid to conſiſt "of 20 cells," whereas it is rather, as in the generic character, an aſſemblage of 20 capſules, coaleſcing when ripe into one pulpy maſs. Curtis and Willdenow have confounded with this genus the *Hibbertia* of Andrews, *Repoſ.* v. 3. t. 126, which the former, by a moſt ſtrange and unaccountable miſapprehenſion, took for the original D. *indica*. The three following are the moſt certain ſpecies of *Dillenia*.

1. D. *ſpecioſa*. Thunb. Tr. of Linn. Soc. v. 1. 200. Sm. Exot. Bot. v. 1. 3. t. 2, 3. (D. indica; Linn. Sp. Pl. 745. Syalita; Rheed. Malab. v. 3. 39. t. 38, 39.) "Leaves elliptic-oblong, ſimply ſerrated. Flowers ſolitary. Stigmas lanceolate." A native of the foreſts of Malabar and Java, where it forms a tree 40 or 50 feet high, with a very thick ſtem, and a rugged bark, which, when wounded, diſcharges an aſtringent watery fluid. The leaves are a foot, more or leſs, in length, crowded about the ends of the branches, on winged footſtalks, oblong inclining to elliptical, ſharply but ſimply ſerrated, furniſhed with one rib and numerous parallel tranſverſe veins, roughiſh but not hairy, except on the back of the veins. Flowers terminal, ſolitary, four or five inches in diameter, fragrant and very handſome, on ſimple round ſtalks. Their petals are white, with ribbed yelloviſh claws. Stamens of a bright full yellow, forming a globeſe denſely imbricated maſs, crowned with the ſtigmas in the form of a white ſtar. The fruit is as big as a man's fiſt, reſembling a large greeniſh apple, but lobed, owing to the five leaves of the calyx, enlarged and become juicy, which compoſe its outſide, enveloping the capſules and their central receptacle, all likewiſe very ſucculent, and conſtituting an eatable, though very acid, fruit, which, as Rheede informs us, requires ſugar, broth, or ſome other addition, to make it palatable. A living plant of this ſpecies was ſent by Dr. Roxburgh to lady Amelia Hume, and is in a thriving condition, being the firſt and only *Dillenia* ever yet ſeen in the gardens of Europe, except ſome young plants raiſed by Mr. Clifford, in Holland, which ſcarcely ſurvived three weeks. In a wild ſtate the tree begins to bear when about four years old, ripening its fruit in December and January.

2. D. *aurea*. Sm. Exot. Bot. v. 2. 65. t. 92, 93. (D. ſerrata; Thunb. Tranſ. of Linn. Soc. v. 1. 201? Sangius; Rumph. Amboin. v. 2. 142. t. 46?) "Leaves elliptic-oblong, doubly ſerrated. Flowers moſtly ſolitary. Stigmas linear." This was gathered by lieutenant-colonel Hardwicke, F.L.S., in thickets to the eaſt of the river Gogra, and other parts of the Eaſt Indies, flowering in April, and ripening fruit in May. The flowers are but half the ſize of the former, yellow, ſtanding either ſolitary or in pairs, on round ſtalks, at the ſummits of the ſmaller branches, and come out before the leaves appear. The latter are deciduous, ſtalked, about ſix inches long, acute, doubly ſerrated, ribbed, and veined like the laſt, their form inclining to obovate. Fruit the ſize of a walnut, of a rich orange-colour throughout, and very juicy. This agrees much with the *Sangius* of Rumphius, which Thunberg adopted from him by the name of *Dillenia ſerrata*, but the leaves in our's are doubly ſerrated, and the flower-ſtalks ſcarcely ternate.

3. D. *pentagyna*. Roxb. Coromand. v. 1. 21. t. 20. Leaves elliptic-oblong, ſimply ſerrated. Flower ſtalks lateral, many together. Stigmas five. Found by Dr. Roxburgh in the vallies far up among the mountains of Coromandel, flowering in March and April. The leaves are as large as thoſe of the firſt ſpecies; the flowers ſmall, yellow, on ſimple ſtalks, growing many together in bundles along the branches. The fruit is pendulous, the ſize of a gooſeberry.

Leſs certain ſpecies are, 4. D. *elliptica*. Thunb. in Tr. of Linn. Soc. v. 1. 200, taken up by that author, without ſeeing it, from the *Songium* of Rumphius, v. 2. t. 45, which Thunberg conceives to be different from D. *ſpecioſa*, to which Linnæus referred it. 5. D. *integra*. Thunb. ib. 199. t. 18. "Leaves obovate, obtuſe, nearly entire." Found in Ceylon. 6. D. *retuſa*. Ibid. 200. t. 19. "Leaves obovate, truncate, ſerrated." From the ſame country. 7. D. *dentata*. Ibid. 201. t. 20. "Leaves obovate, abrupt, toothed. Flowers ſeveral on a ſtalk." Found alſo in Ceylon. Theſe four belong to a genus eſtabliſhed by Rottböll in the New Copenhagen Tranſactions, under the name of *Wormia*. We are not ſufficiently acquainted with its piſtils or fruit to ſay how far it is in thoſe parts diſtinct from the real *Dilleniæ*, which laſt were, in that reſpect, equally unknown to Rottböll. In the 7th ſpecies Thunberg deſcribes three flowers on a ſtalk; our ſpecimen has ſix, forming a ſimple *racemus*.

DILLENIUS, JOHN JAMES, in *Biography*, one of the moſt celebrated botaniſts of the 18th century, eſpecially for his knowledge of Moſſes and their allies, was born at Darmſtadt, in Germany, in 1687. He was educated for a phyſician

ſician in the Univerſity of Gieſſen, and is ſuppoſed to have taken there his degree of doctor of phyſic. At leaſt, he uſed that title before it was conferred on him at Oxford in 1735. During his ſtay at Gieſſen he publiſhed ſeveral papers in the *Ephemerides* of the Imperial Academy *Naturæ Curioſorum*, of which he was an active member. The ſubjects of theſe eſſays were, 1ſt, an examination of ſuch American plants as have been naturalized in Europe; 2d, on the Coffee of the Arabians, with a recommendation of rye as the beſt ſubſtitute for it; 3d, a botanical examination of the *Spergula pentandra*, and ſome plants allied to it; 4th, an account of ſome Cryptogamous plants, as they have ſince been denominated; 5th, on obtaining opium from poppies grown in Germany; and, 6th, a zoological paper on leeches, and two ſpecies of *Papilio*.

In 1719, he publiſhed his *Catalogus Plantarum ſponte circa Giſſam naſcentium*, arranged according to their times of flowering, a method certainly as little ſcientific, and as puzzling as could well be contrived. Accordingly, nothing can be found in ſuch a book but by the index, a method recommended by a recent writer for finding out plants in certain natural ſyſtems; and we believe it to be the moſt infallible. This work of Dillenius, however, contains accurate deſcriptions of many plants before not well determined, with figures, drawn and engraved by himſelf, of the parts of fructification, he having always been laudably anxious to eſtabliſh the genera of plants on ſolid foundations. A criticiſm of the methods of Tournefort, Knaut, and Rivinus, is prefixed to this Flora, by which he gave offence to the latter; and was anſwered by him with ſome degree of aſperity. This drew an acrimonious and rather unfair reply from Dillenius, ſubjoined to ſome copies of the work in queſtion. The reader who troubles himſelf to inveſtigate theſe and ſimilar diſputes, in which the art of man contends with the intricacies of nature, while paſſion and prejudice bewilder both the writer and the reader, will think with ſir Roger de Coverley that "much may be ſaid on both ſides," and perhaps that it might be ſaid a great deal better. Dillenius himſelf ſhewed his wiſdom and ſuperiority ſome time after, when attacked by Threlkeld, an Iriſh writer, by treating his remarks with that ſilent contempt which coarſe miſrepreſentation and envious malignity always feel their ſevereſt puniſhment.

The work above-mentioned procured Dillenius the correſpondence and friendſhip of the excellent and learned William Sherard, who returned in 1718 from Smyrna, where he had been Britiſh conſul, and who, after making a tour on the continent, viſited our author in Germany, and in Auguſt 1721 brought him to England. Here in 1724 Dillenius publiſhed his valuable and popular edition of Ray's *Synopſis*, illuſtrated with 24 plates of his own, and with abundance of remarks, additional plants, eſpecially of the cryptogamous kind, and additional places of growth for many of the rare ſpecies. It has been already obſerved, Tranſactions of the Linn. Soc. v. 4, 277, that "he has, with commendable modeſty and diffidence, diſtinguiſhed from the original work all his own additions, being well aware of the danger of miſtakes. It cannot be concealed that he has added ſeveral plants upon inſufficient grounds, either as ſpecies or natives, and has inſerted others, ſuppoſed to be new, that exiſt under other denominations in the original work. The changes he has made among the ſynonyms, not being always marked, and proving often erroneous, oblige us on that head ſtill to conſult the edition of 1696." On the other hand, Dillenius made ſome uſeful corrections. He diſtinguiſhed and figured the *Hieracium*, afterwards called *alpinum* by Linnæus, which Ray had miſtaken for *H. villoſum quintum* of Cluſius, *villoſum* of Linnæus; a very different ſpecies, ſince obſerved in Scotland. He added much to the graſſes, but rather varieties than ſpecies, which may alſo be ſaid of the mints; but in moſſes, lichens, marine plants, and fungi, he greatly enriched this edition. This book was the chief guide of thoſe who ſtudied Britiſh plants, till Mr. Hudſon's *Flora* appeared in 1762, and its ſelling price has conſiderably encreaſed even ſince that time.

From Dillenius's firſt arrival in England, he had reſided in London, frequently viſiting Eltham in Kent, where Dr. James Sherard, brother of the above William, had a houſe and garden. Hence originated his moſt ſplendid work, the *Hortus Elthamenſis*, publiſhed in 1732, in two volumes folio, with 324 plates, drawn and engraved by his own hand, as were thoſe of his other publications. In theſe plates, 417 ſpecies of plants are delineated with great fidelity. The plates, though not beautiful as engravings, have an air of truth, and a degree of luminous preciſion, which none but a botaniſt can give. They contain almoſt a complete illuſtration of the genus *Meſembryanthemum*, as far as it was then known. Several new genera are here firſt eſtabliſhed, and many obſcure or rare ſpecies elucidated. The letter preſs abounds in ample deſcriptions, elaborate criticiſms, and intelligent remarks, delivered in good language. Some copies were coloured by the author, and are probably very correct, though, as works of art, inferior to what we are accuſtomed to ſee at preſent.

Before the publication of the *Hortus Elthamenſis*, its author was ſettled in the new botanical profeſſorſhip at Oxford, founded by his learned and munificent patron William Sherard, who died in Auguſt 1728. The aim of this gentleman was the continuation of Bauhin's *Pinax*, upon which he had beſtowed great labour and attention, and he left by will 3000*l.* to endow the profeſſorſhip in queſtion for the purpoſe of purſuing his ſcheme, having previouſly built, adjoining to the Oxford garden, a muſeum, to which he bequeathed his library, herbarium, and manuſcripts. He ſtipulated that Dillenius ſhould be the firſt profeſſor, and limited the appointment in future to Doctors of Phyſic, graduates of Oxford, not in holy orders, from among whom the profeſſor is choſen by the London College of Phyſicians. Dillenius ſpent the remainder of his life in the ſtudy of botany, but the *Pinax* never appeared. Botanical publications multiplied ſo faſt, and required ſuch ample pecuniary reſources to obtain them all, that they were quite out of his reach. This is perhaps the leſs to be regretted, as he was not ſupremely accurate in ſynonymy. Indeed the end in view is become rather obſolete ſince the prevalence of the Linnæan ſyſtem of arrangement and nomenclature. All botanical works now ſpeak one language, and for the moſt part wear one form and aſpect, ſo that a general index to them is, in a great meaſure, ſuperfluous. It is, indeed, much to be lamented that the Sherardian and Dillenian *Pinax*, as far as it went, has not been publiſhed, as it probably would prove nearly a complete index to all the botanical knowledge previous to the eſtabliſhment of the preſent clear and ſimple plan of nomenclature. Linnæus viſited Dillenius at Oxford in 1736, and though the latter was previouſly rather unfavourably diſpoſed towards his reformations and innovations, as tending to create difficulty and confuſion in the firſt inſtance, he ſoon forgot all ſuch prejudices, and theſe two great men became mutually attached, as honeſt liberal cultivators of ſo liberal and pleaſing a ſcience ought to be. Dillenius wiſhed to fix Linnæus at Oxford, as his coadjutor in the *Pinax*, and if ſir Hans Sloane had been equally diſcerning and equally liberal, the illuſtrious Swede might have been naturalized amongſt us. Here, however, it is worthy of remark, as we have alluded above to the miſchiefs of literary rivalſhip and enmity, that partiality among philoſophers may ſometimes be no leſs miſchievous.

miſchievous. The errors of Dillenius reſpecting the fructification of moſſes, of which we ſhall ſpeak hereafter, were too implicitly adopted by Linnæus, againſt his own judgment and obſervation; and hence a totally erroneous uſe of terms has prevailed in his works, and thoſe of his followers, to the preſent day. In his *Flora Lapponica* he often cites Dillenius, eſpecially concerning willows, for information reſpecting ſynonyms, that is erroneous; but his own remarks being ſubjoined, we are guarded againſt any errors that might enſue from ſuch high authority. The *Critica Botanica* of Linnæus was dedicated to the Sherardian Profeſſor, as being, from his peculiar occupation and duty, more than any other perſon aware of the evils ariſing from confuſion in botanical nomenclature, and the praiſe and reſpect, habitual in dedications, have rarely been ſo ſincerely beſtowed, or ſo juſtly deſerved. Linnæus remarked, in a letter to Haller, May 1, 1737, that "Dillenius was the only perſon then in England who either cared about, or underſtood the genera of plants;" a degree of ſcientific commendation which, in any age or country, can be extended to very few perſons. Nor did he to whom it was then applied, long continue in the ſame degree to deſerve it. We learn from the correſpondence of Dillenius with Haller, that his whole attention was now abſorbed by the family of Moſſes, under which were included not only the natural order of plants, properly ſo called, but the tribes at preſent denominated *Hepaticæ*, and *Lichenes*, as well as *Byſſi*, *Confervæ*, *Ulvæ*, *Tremellæ*, and others. *Fuci* and *Fungi* were, indeed, the only Cryptogamic families not illuſtrated in the great work upon which the chief reputation of Dillenius now ſecurely reſts, and which appeared in 1741, in one volume quarto, under the title of *Hiſtoria Muſcorum*. It conſiſts of 576 pages, with 85 plates, each containing numerous figures, drawn and engraved by the author. The propoſals promiſed but 464 pages, and 80 plates. The index is one of the moſt ample and complete that any book can boaſt. Of this work 250 copies only were printed; and though the ſubſcription price was no more than one guinea for thoſe printed on ordinary royal paper, and a guinea and half for fine Dutch royal, the book ſold very heavily. Eight copies went to Holland. It found its way alſo into ſome fine Engliſh libraries, and we have known it ſtand, fairly lettered and untouched, on the ſhelves of collectors, as a *hiſtory of the muſcovites*. Some botaniſts, however, acquired and uſed it. Linnæus truſted implicitly to it, and thence adopted ſpecies into his works, as his own ſubſcription copy, on fine paper, evinces. From its being frequently quoted, and the ſubject more ſtudied of late, the price of the *Hiſtoria Muſcorum* is now increaſed more than ten-fold. The plates, with an index or ſynopſis only, were reprinted by Millan in 1763; and even this edition is now advanced in price. The plan of the original one is as complete as poſſible, both with reſpect to the botanical characters and deſcriptions, the ſynonyms and hiſtory, as well as the uſes and qualities of the plants of which it treats. The ſpecific characters, both in Latin and Engliſh, which were intended to ſerve as names, are more ſcientific than thoſe of moſt works of that day, and the varieties under each are carefully inveſtigated. The plates repreſent every ſpecies, often of various ages, and under different forms and appearances, frequently with ſeparate leaves, or other parts. Nothing can be more expreſſive or characteriſtic than theſe figures, except, perhaps, with regard to the cruſtaceous and imbricated Lichens, which are leſs happily repreſented than the reſt. What is chiefly to be regretted, reſpecting the moſſes, is the want of a higher magnifying power, whence the ſtructure of the fringe of the capſule, and innumerable nice marks of diſcrimination in the leaves, or other organs, now familiar to the moſt ſuperficial ſtudent, paſſed unnoticed by Dillenius. On this head, the *Stirpes Cryptogamicæ* of Hedwig have made botaniſts faſtidious; and if that work had been as wide in extent, as excellent in execution, the performance of Dillenius would ſoon have become obſolete, however ſuperior, as beyond all compariſon it is, in botanical learning, and correctneſs of ſtyle. One thing we cannot help regretting, the illiberality with which Dillenius too often ſpeaks of his fellow-labourer in this tribe Micheli, who publiſhed 13 years before him, and had been dead about four years when the work of Dillenius appeared. We are diſguſted with inſinuations, that Micheli delineated or deſcribed more than was to be ſeen in nature; a practice of which that faithful and amiable writer was as incapable, as of the illiberality of gratuitouſly charging another with it. Happily, every one of his obſervations, as far as we can recollect, has been verified by ſubſequent botaniſts, eſpecially the ſeeds of Lichens, *t.* 52, &c. Theſe eminent men fell into one common error, concerning the parts of fructification of moſſes, taking for the anther what is now proved to be the capſule, in which miſtake Dillenius was, as we have already hinted, implicitly followed by Linnæus, and, indeed, by Haller and others, till the Hedwigian ſchool aroſe. Yet Dillenius has eſcaped much of the diſgrace by uſing the word *capſula* for what he believed to be an *anthera*, and Linnæus, from correcting this error, as he thought, has been ſuppoſed the author of the above falſe theory. The part in queſtion is properly called a capſule, but Dillenius miſapplied that term, as he believed it an anther, of which few of his readers are aware. Dr. Pulteney has obſerved, that the *Hiſtoria Muſcorum* was the firſt book printed in England in which any of the Linnæan ſpecific characters were exhibited. The learned Swede communicated ſeveral things to this work, and ſtill continued to correſpond with its author, whoſe laſt letter to him is dated Feb. 10, 1746. In this he aſks for moſſes, and accounts for his not being able to furniſh certain exotic ſeeds which Linnæus had required of him. In an earlier letter he complains of the low and watery ſituation of his Oxford garden, where the heavy morning dews and fogs, in autumn, were extremely unfavourable to the ripening of ſeeds. There appear, in his letters, ſcarcely any traces of the coolneſs or riſing diſpleaſure between theſe old friends, which the letters of Dillenius to Haller ſhew to have exiſted, on his part at leaſt. In a letter to Linnæus, ſo early as April 30, 1741, he complains of growing old, and not enjoying good health. He is ſaid to have been of a ſhort ſtature and corpulent habit, and it is probable he led a ſedentary life. He died of an apoplexy, April 2, 1747, in the 60th year of his age. His place of interment is not recorded, nor does it appear that any monument has been erected to his memory. A portrait of him exiſts in the picture-gallery at Oxford, of which a print has been publiſhed in the *Annals of Botany*, by Dr. Sims and Mr. Konig. The countenance is expreſſive of an eaſy placid diſpoſition, and ſuch is ſaid to have been the character of Dillenius. The imperfections of temper, to ſome indications of which we have alluded above, ſeem not to have been habitual nor permanent. He lived on eaſy terms with thoſe around him, and was reſpected as a man of probity. He was never married, nor have we found mention of any of his relations, except one whom he very eſſentially aided in pecuniary difficulties, to his own great loſs. His drawings, among which are very numerous and valuable repreſentations of Engliſh *Fungi*, his books, manuſcripts, and eſpecially his collection of dried ſpecimens referring to his *Hiſtoria Muſcorum*, were bought of his executor, by his ſucceſſor in the Profeſſorſhip, the late Dr. Humphrey Sibthorp, and are

now in the Sherardian library at Oxford. They have been frequently ſtudied by ſucceeding botaniſts, as may be found recorded in the works of Lightfoot, Dickſon, Turner, and the writer of this article: the preſent amiable Profeſſor, Dr. George Williams, being happy at all times to render them uſeful, and to forward the views of the truly excellent founder. DILLEUGHING. See Tin.

DILLINGEN, in *Geography*, a ſmall town of Germany, in the circle of Swabia, biſhopric of Augſburg, with an univerſity founded by biſhop Otto in 1552, and ſeveral monaſteries and convents of Nuns. It is ſituated on the Danube; 24 miles N.E. of Burgau, 12 N.W. of Augſburg, and as many of Donawerth. Lat. 48° 30'.

DILLON, Wentworth, earl of Roſcommon, in *Biography*, a nobleman diſtinguiſhed for his poetical talents, was born in Ireland about the year 1633. His mother was ſiſter of the great earl of Strafford, and at the ſeat of this nobleman, in Yorkſhire, he was inſtructed in the rudiments of a learned education. Thence he was removed to the univerſity of Caen in Normandy, where he ſtudied under the learned Bochart. He next ſpent ſome time in foreign travel, and became an accompliſhed man, as well as a profound ſcholar. His return to England was ſoon after the reſtoration, when he was made captain of the band of penſioners. At the diſſolute court of Charles II., he became diſſolute, and addicted himſelf to the faſhionable vices and manners of thoſe with whom he lived, and among whom, from his office, he was obliged to aſſociate. At the gaming-table he loſt much of his property, and in diſputes, the conſequences of play, he frequently hazarded his life. On account of a quarrel with the lord privy ſeal, about part of his eſtate, he found it neceſſary to reſign his poſt, and return to Ireland, where he was appointed captain of the guards. His paſſion for gaming ſtill continued, which involved him in ſimilar difficulties to thoſe he had experienced in England. Once, as he returned to his lodgings from a gaming-table, he was attacked in the dark by three ruffians, who had been employed to aſſaſſinate him. The earl, ever courageous, defended himſelf with ſo much reſolution, that he diſpatched one of the aggreſſors, diſarmed another, and obliged the third to ſecure his ſafety by flight. After a few years reſidence in Ireland, he returned to London, and was made, almoſt immediately, maſter of the horſe to the ducheſs of York, and married, about the ſame time, the daughter of the earl of Burlington. Notwithſtanding his diſſolute habits, he was the friend, and, in ſome meaſure, the patron of literature. He now formed the plan of a ſociety for refining the Engliſh language, and fixing its ſtandard: in this he was aided by Mr. Dryden; but lord Roſcommon did not live to bring it to maturity. He never took any lead in politics, but was inclined to high monarchical principles. When James II. aſcended the throne of theſe realms, he formed the reſolution of taking up his reſidence in Rome, but a ſudden fit of the gout, which prevented him from ſetting out on his journey, together with the unſkilfulneſs of his medical attendants, proved fatal. He died in the year 1684, and was buried in Weſtminſter abbey. This nobleman was author of ſeveral poetical pieces, which poſſeſs conſiderable merit. Of theſe the chief is, "An Eſſay on Tranſlated Verſe," a didactic piece, explaining the rules by which tranſlations ſhould be made. He publiſhed, likewiſe, in blank verſe, a tranſlation of Horace's Art of Poetry; a paraphraſe on the 148th pſalm; a tranſlation of the ſixth eclogue of Virgil, of ſome of the odes of Horace, and many ſmaller pieces. In ſpeaking of the powers of this nobleman, Dr. Johnſon ſays, "He is elegant, but not great; he never labours after exquiſite beauties; but ſeldom falls into groſs faults. His verſification is ſmooth, but rarely vigorous, and his rhymes are remarkably exact. He improved taſte, if he did not enlarge knowledge, and he may be numbered among the benefactors to Engliſh literature." Biog. Brit.

DILLSBERG, in *Geography*, a town of Germany, in the circle of the Lower Rhine, and palatinate of the Rhine; 6 miles E. of Heidelberg.

DILLWYNIA, in *Botany*, ſo named by Dr. Smith in honour of Mr. Lewis Weſton Dillwyn, F.R.S., F.L.S., author of an eminently valuable work on Britiſh *Conferva*. Sm. in Sims' and Konig's Annals of Botany, v. 1. 510. Claſs and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, ſect. 4. Juſſ.

Gen. Ch. *Cal.* Perianth bell-ſhaped, two-lipped, without appendages; angular at the baſe: upper lip of 2 oblique, divaricated ſegments: lower of 3 direct, nearly equal ones. *Cor.* papilionaceous, of 5 petals; ſtandard broad, almoſt kidney-ſhaped, with a linear claw of its own length; wings obovate, ſhorter than the ſtandard, each with an incurved tooth on its upper edge near the baſe; keel ſhorter than the wings, of 2 petals, each with a tooth at the upper edge. *Stam.* Filaments 10, ſeparate, awl-ſhaped, aſcending, the lowermoſt gradually longer, all incloſed in the keel; anthers roundiſh, 2-lobed. *Piſt.* Germen ſuperior, oblong; ſtyle ſhort and thick, bent upwards; ſtigma obtuſe, downy. *Peric.* Legume ovate, inflated, of one cell. *Seeds* 2, kidney-ſhaped, ſmooth, each with a white gland-like appendage.

Eſſ. Ch. Calyx five-cleft, two-lipped. Corolla papilionaceous. Style recurved, ſhorter than the germen. Stigma obtuſe, downy. Legume inflated, of one cell, with two ſeeds.

Sp. 1. D. *ericifolia*. Sm. Exot. Bot. v. 1. 47. t. 25. "Leaves linear, twiſted, rough with minute points. Flowers nearly terminal." Stem ſhrubby, 4 or 5 feet high, much branched, ſpreading; the branches cluſtered, ſlender, rigid, leafy, clothed when young with ſhort, denſe, prominent pubeſcence. *Leaves* ſcattered, numerous, ſpreading, on ſhort ſtalks, linear, narrow, acute, entire, revolute, rough, with ſmall points, twiſted ſo that their convex under ſide is turned uppermoſt; the other ſide is marked with a longitudinal furrow. *Stipulas* minute, gland-like, one on each ſide of the footſtalk at its baſe. *Flower-ſtalks* cluſtered about the ſummits of the branches, rarely lateral. *Bracteas* numerous, concave, at the baſe of the flower-ſtalks, with a pair towards their middle. *Flowers* elegant, but inodorous. *Calyx* fringed at the edge with white denſe woolline's, otherwiſe ſmooth, and often reddiſh. *Petals* of a golden hue, not changed by drying; the ſtandard marked with a crimſon radiating central ſpot. *Legume* ſomewhat hairy, crowned by the thick baſe of the ſtyle.—This was one of the firſt plants whoſe ſeeds or dried ſpecimens were brought to England from New South Wales, and it flowered in the London nurſeries about the year 1793. It is eaſily propagated by ſeed, and only requires in winter the ſhelter of a greenhouſe, with regular but moderate ſupplies of water, and a turfy ſoil with ſome loam. 2. D. *floribunda*. Sm. Exot. Bot. t. 26. "Leaves linear, ſomewhat twiſted, rough with tubercles. Flowers lateral, axillary." A rather larger ſhrub than the laſt, brought from the ſame country. *Leaves* leſs ſpreading and more crowded, as well as broader, and covered with coarſe callous tubercles. *Stipulas*, as far as we have diſcovered, wanting. *Flowers* copious, lateral, axillary, ſolitary, on ſhort bracteated ſtalks, their ſtandard ſcarcely ſo broad

broad in proportion to its length, but otherwiſe much like the former. *Legume* very hairy, crowned with the ſmooth ſtyle. 3. D. *glaberrima.* Sm. in Ann. of Bot. v. 1. 510. Labillard. Nov. Holl. v. 1. 109. t. 139. "Leaves linear, ſtraight, triangularly keeled, ſmooth. Flowers terminal, crowded." This is ſmaller and more ſlender than either of the foregoing, with perfectly ſmooth *leaves*. *Stipulas* awl-ſhaped, minute. *Flowers*, as far as we can learn from the dried ſpecimens, moſt like the firſt ſpecies. This plant, though found about Port Jackſon, New South Wales, has never yet been cultivated in England. 4. D. *myrtifolia.* Sm. in Tr. of Linn. Soc. v. 9. (D. obovata; Labillard. Nov. Holl. v. 1. 110. t. 140?) "Leaves decuſſated, obovate, ſlightly concave, obſcurely five-ribbed, ſmooth. Flowers axillary." Communicated to the author by Mr. Menzies, who gathered it at King George's Sound on the weſt coaſt of New Holland. It has not been ſeen alive in Europe. It ſeems a very buſhy ſhrub. The *branches* are ſmooth and angular. *Leaves* crowded, oppoſite, croſſing each other in pairs, obovate, ſtalked, entire, ſmooth, tipped with a pungent point, and marked with 5 ribs, 2 of which are leſs conſpicuous than the reſt. The upper ſide is much the paleſt; the under purpliſh. *Stipulas* minute, ovate, fringed. *Flowers* ſeemingly like thoſe of the ſecond ſpecies. If this be the *obovata* of M. Labillardiere, which ſeems probable, our name muſt give way to the right of priority. 5. D. *glycinifolia.* Sm. in Tr. of Linn. Soc. v. 9. "Leaves ovate or linear, revolute, reticulated. Flowers racemoſe." This alſo is known to us merely by ſpecimens gathered at King George's Sound by Mr. Menzies. Its habit is very unlike the reſt, and more reſembles ſome of thoſe ſimple-leaved plants now referred to *Glycine*; ſee Curt. Mag. v. 8. t. 263. The *ſtyle* is "ſo recurved as almoſt to form a circle, not ſtraight at the baſe and then ſuddenly hooked, as in the genuine *Dillwyniæ*." The *legume*, moreover, is unknown, and when diſcovered, may ſtamp the plant as a new genus. The *calyx* and *corolla* ſufficiently accord with that to which it is here referred. S.

DILUENTS, in *Medicine*, are thoſe liquors which increaſe the fluidity of the humours in the animal body.

It is well known that the ordinary fluidity of the blood is owing to water, which, in great proportion, is conſtantly preſent in it; and that the chief, and, perhaps, only means of increaſing its fluidity, will be by increaſing the proportion of water in it. The ſame may be ſaid, indeed, of the ſecreted and excreted fluids in general, ſo that water may be conſidered as the only proper general diluent.

Nature having appointed water to be univerſally the drink of the whole animal creation, it is, therefore, in man, the proper object of thirſt; and its firſt operation is to quench this appetite, and thereby remove a very uneaſy ſenſation, which is often, in febrile diſeaſes particularly, a conſiderable irritation of the whole ſyſtem. It does this not only by its coolneſs and ſimple fluidity, but alſo by its diluent power, in diſſolving the viſcid matter of the mouth and internal fauces.

As the greater part of mankind take drink along with their ſolid food, there can be little doubt that a certain portion of diluent drink, and particularly of water, taken into the ſtomach, favours the ſolution and digeſtion of the ſolid aliment, and alſo contributes to the more ſpeedy evacuation of the ſtomach. The quantity neceſſary for this is very different in different perſons, and muſt be ſuited to the feelings of every individual; but with this obſervation, that a larger proportion than neceſſary, by increaſing the diſtenſion of the ſtomach, contributes to take off what appetite might otherwiſe remain; and it is commonly proper, only, after the digeſtion is over, to throw in a quantity of water to finiſh that buſineſs more completely, and to promote the entire evacuation of the ſtomach. But this diluent is not only neceſſary for the aſſiſtance of digeſtion, but otherwiſe, alſo, to the ſtate of the ſtomach itſelf. As the mucous glands of this organ throw out a large quantity of a heavy viſcid fluid, which, remaining in the ſtomach, gives an uneaſy ſenſe of weight, and impairs the appetite; ſo in this morbid ſtate, a quantity of water, by diluting and favouring the abſorption and evacuation of this mucus, may often be the moſt certain remedy.

When water is carried into the inteſtines, it will, by mixing with the bile, diminiſh the acrimony of this fluid, and obviate irritations that might otherwiſe have thence ariſen. By diluting the contents of the inteſtines, it will certainly promote the more entire ſolution of theſe, and even, by its bulk, favour their progreſs: and the dilution may likewiſe favour the abſorption of the finer and nutritious parts by the lacteals. A large quantity of water, quickly taken, and paſſing into the inteſtines, may, by its bulk, increaſe their action, and thus prove laxative: in this way water has been known, in numerous inſtances, to prove a very uſeful remedy, by clearing out the whole of the contents, whether natural or morbid, which might be ſtagnant there. The common people, who commonly take every thing that has the name of a mineral water, in very large quantities, often thus obtain much benefit from waters of no ſenſible impregnation.

When any unuſual quantity of water enters the lacteals or other abſorbents, it muſt contribute to increaſe the fluidity of their contents, and to expedite their motions, and perhaps to keep up the free paſſage through the conglobate glands, which are liable to obſtructions. When water enters the blood-veſſels by the thoracic duct, it muſt, in proportion, increaſe the fluidity of the whole maſs of blood, and is certainly the means by which its fluidity is ordinarily preſerved. But, in healthy bodies, or ſuch as are without any obſtruction of the excretions, any unuſual diſtenſion of the veſſels cannot in this way be produced, or long ſubſiſt; for it is not to be doubted that ſuch increaſed quantity of water in the blood, will immediately paſs off by one or other of the excretions: and this effect of diluents is important in the treatment of diſeaſes.

From this detail of the effects of water, when taken freely into the body, it will readily appear that the abundant uſe of it, with very few exceptions, may be conſidered as a very general means of preſerving the health, and that it is an important agent in the cure of many diſeaſes.

In the firſt place, by removing the diſagreeable ſenſation of thirſt, which is common in febrile diſeaſes, dilution removes one of the irritations which tend to keep up the febrile ſtate. And, ſecondly, by the diſpoſition of diluents to paſs off by the excretions, they tend to diminiſh fevers by exciting a regular perſpiration. In many diſordered ſtates of the ſtomach and other organs of digeſtion, which attack the ſedentary and indolent, and thoſe of irregular habits of life, and are included under the term *bilious*, diluents, by aiding digeſtion, and the evacuation of the ſtomach and duodenum, are of great utility, and much of the effect of all mineral waters, on the hypochondriac and other invalids, who frequent watering places, is to be attributed to the ſimple dilution. By theſe means, and by its paſſage through the abſorbent, and glandular ſyſtems, water freely taken is ſignally beneficial in the cure of ſcrofulous obſtructions; and the pureſt waters, with the leaſt ſenſible impregnation, have been particularly extolled for their virtues againſt this diſeaſe. Thus Ilkley ſpa has been

celebrated by Dr. Moſſman; and at Rheims, the water, which was extremely pure, was ſo renowned for the cure of ſcrofula, that an hoſpital, for the reception of patients labouring under that malady, was erected there.

Diluents, in conſequence of their diſpoſition to paſs off by urine, eſpecially when perſpiration is not encouraged, are uſeful in allaying the pain of ſtrangury and ardor urinæ, by diluting the acrimonious ſalts of the urine, and thus diminiſhing the irritation which they would excite in paſſing the neck of the bladder and the urethra, when rendered acutely ſenſible by inflammation. It is, doubtleſs, to the quantity of diluents taken in, with demulcent medicines, rather than to any ſpecific effects of the latter, that this ſucceſsful operation is to be attributed. See Demulcent.

All aqueous liquors, that is, all liquors conſiſting chiefly of water, without the addition of other matters, that may either diminiſh the diluent qualities of it, or give it peculiar properties, are to be conſidered as diluents operating in the way above deſcribed, and poſſeſſing the properties of ſimple water. See Cullen, Materia Medica, vol. ii.

DILURO, in *Ancient Geography*, a river of Spain, according to Ptolemy, called by Pliny Iluro, and by Mela Eluro.

DIMA, or Dyma, in *Ancient Geography*, a town of Thrace.

DIMACHÆ, from δις, *double*, and μαχω, *I fight*, in *Antiquity*, a kind of horſemen, firſt inſtituted by Alexander. Their armour was lighter than that of the infantry, and at the ſame time heavier than that uſed by horſemen, ſo that they could act as horſe or foot as occaſion required.

DIMACHÆRUS, Διμαχαιρος, from δις, and μαχαιρα, *ſword*, a gladiator who fought with two ſwords.

DIMALUM, in *Ancient Geography*, a town of Illyria, according to Polybius, called Dimallum by Livy.

DIMBACH, in *Geography*, a town of Germany, in the archduchy of Auſtria; 4 miles N. of Grein.

DIMCHURCH, or Dinchurch, a village of England, in the county of Kent, ſituated by the ſide of a ſtrong dyke, called "Dimchurch wall," between Romney and Hythe, to prevent the encroachments of the ſea, with a carriage road on the ſummit, wide enough in general for carriages to paſs each other; $4\frac{1}{2}$ miles N.N.E. of New Romney, and $4\frac{1}{2}$ S.S.W. of Hythe.

DIMENSION, the extenſion of a body, conſidered as meaſurable.

Hence, as we conceive a body extended, and meaſurable in length, breadth, and depth, we conceive a trine dimenſion, *viz.* length, breadth, and thickneſs. The firſt called a line, the ſecond a ſurface, the third a ſolid.

Dimension is particularly uſed with regard to the powers of the roots, or values of the unknown quantities of equations, which are called the dimenſions of thoſe roots. See Equation and Root.

Thus in a ſimple equation, the unknown quantity is only of one dimenſion, as $x = a + b$. In a quadratic equation it is of two dimenſions, as $x^2 = a^2 + b^2$. In a cubic, of three, as $x^3 = a^3 - b^3$, &c.

DIMETER. See Iambic.

DIMETIENT, in *Geometry*, is ſometimes uſed for diameter.

DIMIKUR, in *Geography*, a town of Bohemia, in the circle of Konigingratz; 10 miles W. of Biezow.

DIMINISHED Interval, in *Muſic*. See Interval.

Diminished *ſecond* is a ſemitone major, leſſened by a ſemitone minor. See Interval and Second.

Diminished *third*, by ſome called defective third, is properly a third minor leſſened by a ſemitone minor. But among practical muſicians it commonly ſignifies an interval equal to two ſemitones major. And this they confound with the former; but there is a difference between them, equal to the difference between a tone-major and minor, that is, a comma. The firſt mentioned of theſe diminiſhed thirds will be expreſſed by $\frac{144}{125} = \frac{4}{5} : \frac{25}{24}$, and is equal to the tone-major and enharmonic dieſis; for $\frac{144}{125} = \frac{9}{8} \times \frac{128}{125}$. The ſecond diminiſhed third will be expreſſed by $\frac{256}{225} = \frac{16}{15} \times \frac{16}{15}$, which is a comma leſs than the former. See the table in the article Interval.

Diminished *fourth*. See the table in the article Interval.

The diminiſhed fourth often occurs in practice, as from C to G ♮ deſcending; and ſometimes, though more rarely, from G ♮ to C aſcending.

Diminished *fifth*, is leſs than the true fifth by a ſemitone minor, and is therefore equal to two leſſer thirds.

Practitioners often confound the diminiſhed fifth with the ſemi-diapente, or falſe fifth, which is a comma leſs. See Interval.

Diminished *ſixth*. This interval, according to Ozanam, contains two tones and three ſemitones major; or a fourth and diminiſhed third; or a diminiſhed fourth and third minor. Thus from C ♮ to A ♭ is a diminiſhed ſixth.

But as there are two diminiſhed thirds, ſo there may be as many diminiſhed ſixths; theſe being the complements of the former to the octave. One of theſe diminiſhed ſixths will be expreſſed by $\frac{1024}{675} = \frac{4}{3} \times \frac{256}{225}$, and this is a ſemitone major more than the ſemi-diapente; the other diminiſhed ſixth will be $\frac{676}{375} = \frac{4}{3} \times \frac{144}{125}$, which is a ſemitone minor leſs than the flat ſixth. Practitioners confound theſe two; and, in effect, in temperate ſcales they coincide, as do all other intervals differing only by a comma. See Temperament.

Diminished *ſeventh* is of two kinds, differing by a comma. See the table in the article Interval.

That diminiſhed ſeventh, which is the complement of the ſuperfluous ſecond to the octave, is the only one in uſe. It is a ſemitone major more than the ſixth minor, as from C ♮ to B ♭.

Diminished *octave*, is a ſemi-tone minor, leſs than the octave, as from C to *c* ♭. It occurs ſometimes in the baſſes of inſtrumental pieces of muſic. See Interval.

DIMINUE', *Fr.* is a term uſed in muſic for an extreme flat 7th, produced by a ſharp to the loweſt note, or a flat to the higheſt; as $\frac{f\ ♮}{G\ ♯}$ or $\frac{B\ ♭}{C\ ♯}$.

DIMINUITO, *Ital.* an interval in muſic not accurate in its extent, that is, from being too flat, or too ſharp, out of tune.

DIMINUTION, in *Architecture*, a contraction of the upper part of a column, whereby its diameter is made leſs than that of the lower part.

To attain thoſe two important points in architecture, ſtrength, and the appearance of ſtrength, all architects have made their columns leſſer above than below, which is called their diminution. Some have likewiſe made them a little bigger towards the middle than at the bottom, which is called their ſwelling. The Gothic architects, indeed, obſerve neither diminution nor ſwelling; their columns are perfectly cylindrical; for which reaſon they are properly called pillars, in contradiſtinction to columns.

The diminution generally commences from one third of the height of the column. Some make it begin from the very baſis, and hold tapering to the capital; but that has not ſo good an effect. Vitruvius would have the diminution of columns differ according to their height, and not according to their diameter: thus, a column of fifteen feet high, he diminiſhes a ſixth part of its diameter; and another of fifty

feet only an eighth part; but we do not find this rule obſerved in the antique. The difference of orders, M. Perrault obſerves, does not infer a difference of diminution, there being ſmall and great diminutions in different works of the ſame order; excepting, however, the Tuſcan, which Vitruvius diminiſhes by a fourth part, though Vignola only makes it a fifth, and the Trajan column a ninth. The diminutions are very differently adjuſted in the different antique buildings, as well as by the different modern authors. For the method of diminiſhing a column, ſee COLUMN.

DIMINUTION, in *Heraldry*, a term uſed by Latin writers for what we more uſually call differences, and the French briſures. See DIFFERENCE.

DIMINUTION, in *Law*, is where the plaintiff or defendant in a writ of error alleges to the court, that part of the record remains in the inferior court not certified, and therefore prays that it may be certified by certiorari. Diminution cannot be alleged of what is fully certified, but of ſomething that is wanting, as the want of an original, or a warrant of attorney.

DIMINUTION, in the *Old Muſic*, is changing, in a canon, ſemibreves to minims. It likewiſe meant variations, diviſions, breaking crotchets into quavers, quavers into ſemiquavers, &c.

DIMINUTION, in *Rhetoric*, the augmenting and exaggerating what you have to ſay, by an expreſſion that ſeems to weaken and diminiſh it.

As for inſtance, when a man ſays, with a certain tone, This woman is not ugly; meaning, ſhe is very handſome.

Some authors take diminution in a ſtricter ſenſe, *viz.* for ſaying leſs than a man really means; as, You are not, indeed, to be commended; where a greater reproach is ſecretly meant.

DIMINUTIONE, *Ital.* in *Muſic*, is one of the names given to figurative counterpoint, to diſtinguiſh muſic in parts of note againſt note, or plain counterpoint from florid. See DIMINUITO.

DIMINUTIVE. in *Grammar*, a word formed from ſome other, to ſoften or diminiſh the force and effect thereof; or to ſignify a thing that is little in its kind.

Thus cellule is a diminutive of cell, globule of globe; hillock of hill, &c.

The Italians abound in diminutives, every author being at liberty to make as many as he pleaſes. The French are much more reſerved in that reſpect, though their old authors were every whit as licentious as the Italians, witneſs Belleau, &c.

In Engliſh we have very few; not that, as ſome have ſaid of the French, our language is hard, and incapable of the ſofteſt expreſſions, but becauſe we lay all our tenderneſs in our ſentiments; or rather, our language is tender, like a perſon of diſcretion, who always ſpeaks ſenſe, even in ſpeaking of his paſſion.

In Latin, Italian, Engliſh, and moſt other tongues, diminutives are formed from primitives, by the addition of a few letters or ſyllables: in French, the caſe is frequently otherwiſe, the diminutive being ſometimes ſhorter than the primitive, ſometimes of the ſame length.

They have a pleaſing effect in that celebrated addreſs of Adrian to his departing ſoul, which begins,

> " Animula, vagula, blandula
> Hoſpes comeſque corporis, &c."

Some grammarians call *at leaſt* a diminutive conjunction, as ſerving to leſſen or diminiſh the force of what went before.

DIMISSORY LETTERS, *Literæ Dimiſſoriæ*, in the *Canon Law*, a letter given by a biſhop to a candidate for holy orders, having a title in his dioceſe, directed to ſome other biſhop, and giving leave for the bearer to be ordained by him.

When a perſon produces letters of ordination, or tonſure, conferred by any other than his own dioceſan, he muſt at the ſame time produce the letters dimiſſory, given by his own biſhop, on pain of nullity.

Letters dimiſſory cannot be given by the chapter, ſede vacante; this being deemed an act of voluntary juriſdiction, which ought to be reſerved to the ſucceſſor.

DIMITRIA, in *Geography*, a fort of Ruſſian Tartary, on the Don, in the government of Caucaſus; 12 miles N. of Ekaterinograd.

DIMITROW, a town of Poland, in the palatinate of Braclaw; 50 miles S. S. W. of Braclaw.

DIMITY is a kind of cotton cloth originally imported from India, and now manufactured in great quantities in various parts of Britain, eſpecially in Lancaſhire. Dr. Johnſon calls it dimitty, and deſcribes it as a kind of fuſtian. The diſtinction between fuſtian and dimity, in the ſenſe in which theſe words are generally underſtood, ſeems to be this; that the word fuſtian is uſed to expreſs a common tweeled cotton cloth of a ſtout fabric, upon which no ornament is woven in the loom; but which is moſt frequently dyed after being woven. Dimity is alſo a ſtout cotton cloth of a ſimilar fabric; but is ornamented in the loom, either with ſtripes or fanciful figures, and when woven is ſeldom dyed, but commonly bleached of a pure white. The ſtriped dimities are the moſt common, as they require leſs labour in weaving than the others, and the mounting of the looms being more ſimple, and conſequently leſs expenſive, they can be ſold at much lower rates. For the plans of mounting both kinds, as generally practiſed by weavers, ſee the article DRAUGHT and *Cording*.

DIMIZA, in *Ancient Geography*, a town of Aſia, in Media Minor.

DIMLU, in *Geography*, a ſtrong city of Arabia, in the diſtrict of Hodsjerie, a part of the Imam's dominions, ſeated upon a mountain, and called by Abulfeda the king's treaſury; 20 miles E. S. E. of Taas.

DIMNAH, in *Ancient Geography*, a town of Zebulun, given to the Levites of Merari's family.

DIMNE, in *Geography*, a town of Arabia, in the country of Yemen; 12 miles S. S. E of Dsjebi.

DIMNESS *of Sight*, in *Farriery*, a diſorder in horſes, proceeding from blood-ſhotten eyes. If the ball of the eye be ſound, the cure is effected by keeping the horſe warm, with a hood of linen cloth fitted to his head, and anointing the eye-lids twice a day with a compoſition of ſugar-candy, honey, and white roſe-water. In two or three days the eyes will be well, after which the creature ſhould be blooded.

In this diſorder the bladders on any part of the eye ought by no means to be clipped or meddled with. See SIGHT.

DIMOCARPUS, in *Botany*, a name given by Loureiro to the Chineſe fruits Litchi and Longan. See SCYTALIA.

DIMŒRITÆ, in *Eccleſiaſtical Hiſtory*, a name given to the Apollinariſts, who at firſt held, that the Word only aſſumed a human body, without taking a reaſonable ſoul like ours; but being at length convinced by formal texts of Scripture, they allowed, that he did aſſume a ſoul, but without underſtanding; the Word ſupplying the want of that faculty. From this way of ſeparating the underſtanding from the ſoul, they became denominated dimœritæ, *q. d.* dividers, ſeparaters, of δια and μοιραω, *I divide*.

DIMON, GREATER, in *Geography*, one of the Feroe iſlands, lying half a Daniſh mile S. S. E. from Skuoe, and

$\frac{2}{3}$ of a mile S. S. W. from Sandoe. Its length, from S. E. to N. W., is ſcarcely half a mile, and its breadth about one-eighth of a mile. The coaſt is almoſt everywhere high and ſteep, and is acceſſible only in two places, where only one perſon can aſcend at a time; ſo that no iſland can be better fortified by nature. It is, indeed, impregnable; for it is impoſſible to ſtarve the inhabitants, as it abounds with good fiſh and ſea-fowls, and no ſhip can remain near it on account of the force of the currents. The fowls are ſo numerous, that at certain periods they almoſt darken the air, and ſtun the ears with their piercing cries. The whole population of the iſland conſiſts of one family; and in ſummer, the only time when the clergyman can viſit the church, it is neceſſary to hoiſt him up into the iſland by means of a rope. On the ſummit, however, the iſland is pretty level; but on account of the ſteepneſs of the coaſt, no boats can be kept here, and, therefore, the inhabitants live in a ſtate of ſeclufion from other people, and can never quit their priſon, except when ſome of the inhabitants of the other iſlands come to them with a boat.

Dimon, *Leſſer*, another of the Feroe iſlands, which lies at the diſtance of $\frac{3}{4}$ of a Daniſh mile from the greater Dimon, and about the ſame from the Suderoe. It is a ſmall uninhabited iſland, nearly of a circular form, $\frac{1}{6}$th of a mile in diameter. The ſurrounding coaſt is very ſteep, and is acceſſible only in three places. In form it reſembles a hay-ſtack, and, when viſible, might ſerve as a land-mark to navigators. It abounds with ſea-fowl, and contains a great number of wild ſheep. The black wild ſheep of this iſland are ſuppoſed to be a peculiar ſpecies; they are ſmall in ſize, have ſhort-curled wool, and do not readily mix with the others introduced into this iſland; their fleſh, which has a dark appearance, in taſte approaches to that of other wild animals. They ſhelter themſelves from the ſeverity of the weather in ſome natural caverns found in the iſland; and when the inhabitants of Suderoe come hither for a few days to catch ſea-fowl, they take up their abode in caverns of the ſame kind.

DIMONA, in *Ancient Geography*, a town of Lower Mœſia, ſeated on the bank of the Danube.

Dimona, a town of Judea, in the ſouthern part of the tribe of Judah, Joſhua, xv. 22.

DIMORPHA, in *Botany*, (from δις, *double*, and μορφη, *form*, alluding to the differences of ſtructure in the two genera of Aublet, which are by Schreber united into one under this name.) Schreb. Gen. 493. Willd. Sp. Pl. v. 3. 971. Mart. Mill. Dict. v. 2. (Parivoa; Aubl. Guian. v. 2. 756. t. 303, 304. Juſſ. 350. Eperua; Aubl. Guian. v. 1. 369. t. 142. Juſſ. 349. Panzera; Willd. Sp. Pl. v. 2. 540.) Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Leguminoſæ*, ſect. 3. Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, rounded at the baſe, divided into three or four deep ſegments, obtuſe. *Cor.* Petal one, very large, ventricoſe, rolled in at the ſides, finely crenate, inſerted into the calyx under the ſtamens, and placed at the lowermoſt ſide. *Stam.* Filaments diadelphous, (the ſimple one being at the opening between the edges of the petal, and the nine united ones lying againſt the middle of the petal,) all aſcending, longer than the corolla; anthers oblong, quadrangular, incumbent. *Piſt.* Germen ſtalked, compreſſed, ſhort; ſtyle longer than the ſtamens; ſtigma ſimple. *Peric.* Legume large, oblique, compreſſed, of one cell. *Seeds* ſolitary, or very few.

Obs. The petal is ſingle as in *Amorpha*, but it occupies the place of the keel, (not of the ſtandard;) the latter, as well as the wings, are wanting. In the *Parivoa* of Aublet the legume is obovate, and ſingle-ſeeded; in *Eperua* the filaments are thickened and villoſe at their baſe, (in his figure five only have anthers,) and the legume is ſcymitar-ſhaped, with three or four ſeeds. Schreb.

Eſſ. Ch. Calyx in three or four deep ſegments. Keel of one ample inflated petal. Wings and ſtandard wanting. Legume compreſſed, with few ſeeds.

It is very probable that Juſſieu and Willdenow may be right in keeping theſe two genera of Aublet diſtinct, but we have none of us ſufficient materials to determine the point, Aublet's figures, made from dried ſpecimens, and thoſe ſpecimens themſelves, (in this caſe imperfect,) being our only guides, except his original French deſcriptions, of which the Latin is a tranſlation. The only ſpecies known are,

1. D. *grandiflora*. Willd. Sp. Pl. v. 2 971. (Parivoa grandiflora; Aubl. t. 303.) "Leaves abruptly pinnated. Legume ſmooth." A lofty tree found about the ſhores of creeks and rivers in Guiana, flowering in September. The *leaves* conſiſt of three or four pair of ovate, pointed, ſtalked, ſhining leaflets, ſometimes $3\frac{1}{2}$ inches long. *Flowers* large, purpliſh, in terminal cluſters. *Legume* thick, woody, containing one large ſeed. 2. D. *tomentoſa*. Willd. (P. tomentoſa; Aubl. t. 304.) "Leaves ternate or pinnate. Legume downy." Native of the ſame country, in moiſt meadows, and about rivers. This tree is about 25 feet high. *Leaves* of three or five leaflets. *Flowers* in terminal ſpikes, purpliſh, and agreeing in ſtructure with thoſe of the firſt ſpecies, but the *legume* is downy. 3. D. *falcata*. (Eperua falcata; Aubl. t. 142. Panzera falcata; Willd. Sp. Pl. v. 2. 540.) Leaves abruptly pinnated. Legume ſmooth, with three or four ſeeds. Found in the foreſts of Guiana, near rivers, flowering in September. The *trunk* is 50 or 60 feet high. The wood oily, laſting long in a moiſt ſituation, and preferred by the negroes for the handles of their hatchets. *Leaves* reſembling thoſe of the firſt ſpecies, but their leaflets are more elliptical. *Flowers* red, in cluſters, on very long, axillary, compound, pendulous ſtalks. *Legume* ſeven inches long, ſcymitar-ſhaped, containing three or four flat ſeeds, of an irregular form.

DIMORPHOTHECA, a name given by Vaillant to a genus of plants, which Linnæus makes the ſame with the calendula.

DINA, in *Ancient Geography*, a lake of the Peloponneſus, in Arcadia. Pauſanias.

DINABURG, in *Geography*, a town of Ruſſia, in the government of Polotſk, ſeated on the Dwina; 80 miles N. W. of Polotſk, and 256 S. S. W. of Peterſburg. N. lat. 56° 5′. E. long. 61° 46′.

DINAGEPOUR, a town of Hindooſtan, in the country of Bengal; 85 miles N. of Moorſhedabad, and 180 E. of Patna.

DINAITES, in *Scripture Hiſtory*, a people who oppoſed the rebuilding of the temple. Ezra, iv. 9.

DINAN, a town of France, in the department of the Côtes du Nord, chief place of a diſtrict, ſituated on the river Rance, 18 miles S. of St. Malo, 36 N. W. of Rennes, and 270 N. W. of Paris. W. long. 1° 59′. N. lat. 48° 27′ 16″. It contains a population of 4170 individuals, and is divided into two parts, eaſt and weſt, each of which is a ſeparate canton. The eaſt compriſes ſix communes and 11,906 inhabitants; the weſt 13 communes, and 12,642 inhabitants. Both together have a territorial extent of $217\frac{1}{2}$ kiliometres.

Dinan is one of the nine quarters of the maritime diſtrict of Breſt, and has in its naval conſcription the leſſer places of Pleudihem, Plouer, Pleuſtuit, Saint Egouat, Saint Briac, and Saint Jacut. But it is chiefly celebrated for its mineral waters, on which account it is much frequented even by foreigners. The water has been carefully analyſed by Mr. Monnet

Monnet in 1769. It contains carbonate of iron, muriate of ſoda or potaſh, and carbonate of earth, (carbonate terreux.) Its taſte is ferruginous. On iſſuing from the ſource it is perfectly pellucid, but if left expoſed to the air it grows muddy, and leaves at the bottom of the veſſel in which it is contained an ochreous ſediment. The water then loſes its metallic taſte, and becomes inſipid, like common water. It ought, therefore, to be drank at the ſpring, and taken cold, as it is altered by heat. Its effects are aperitive, deterſive, aſtringent, and corroborative. The uſe of this water is particularly recommended in female diſeaſes ariſing from deficient or ſuperabundant menſtrual diſcharges.

As chief place of a diſtrict, Dinan has a ſub-prefect, a court of juſtice, and a regiſter office. The whole diſtrict contains 10 cantons, 92 communes, and 96.327 inhabitants, upon a territorial extent of 1460 kiliometres. The ſoil is good, and produces abundance of corn, hemp, and flax. Theſe articles, together with cattle, fiſh, honey, wax, linen cloth, iron, and ſome pottery, conſtitute the principal trade of the diſtrict of Dinan.

DINANT, a ſmall town of France, in the department of Sambre and Meuſe, chief place of a diſtrict, ſituated on the right ſhore of the Meuſe, between the river and a ſteep rock, which renders it very narrow, 18 miles S. of Namur, 45 S. E. of Mons, 48 S. W. of Liege. Lat. 50° 15′. It has a population of 2964 individuals. The canton contains 36 communes and 10,051 inhabitants, upon a territorial extent of 245 kiliometres.

As chief place of a diſtrict, Dinant has a ſub-prefect, a court of juſtice, and a regiſter-office. The ſoil of the diſtrict is tolerably fertile. There are ſome iron mines, rich quarries of white, black, and red marble, copper founderies, forges, tan-yards and breweries. Leather, copper utenſils, bar-iron, wrought iron, and beer, conſtitute the principal articles of trade.

The diſtrict of Dinant compriſes five cantons, 137 communes, and 37,321 inhabitants, upon a territorial extent of 1177½ kiliometres.

Dinant, a bay of France, on the W. coaſt of the department of Finiſterre, in the Engliſh channel, between Breſt road and the bay of Douarnenez. N. lat. 48° 13′. W. long. 14° 43′.

DINAPORE, a village of Hindooſtan, in the diſtrict of Patna, lies about 14 coſs W. of Bankipore, one of the ſuburbs of Patna, in which the Eaſt India company's civil ſervants reſide. At Dinapore there is a military cantonment built by the company on the ſame elegant and magnificent ſcale with thoſe at Berhampoor and Calcutta. It is ſo extenſive that every officer enjoys nearly three times the accommodation afforded by any of the barracks in England. The private ſoldiers are alſo provided with large and well-aired lodgings; but the troops belonging to the native battalions are quartered in ſmall tents, a little ſuperior to thoſe of the natives. For ſeveral miles around the adjoining villages of Bankipore and Dinapore, the fields aſſume the appearance of a rich and well-dreſſed garden. The ſurface of the ground in this flat part of the province of Bahar does not riſe more than 30 feet above the level of the Ganges; and in many places its level is ſtill more inconſiderable. The water therefore is not more than two or three fathoms from the ſurface; and the method of raiſing it is very ſimple. Two long bamboos are raiſed upon a frame about 10 or 12 feet, which are wrought like levers by a weight attached to one end, as the moving power which raiſes the leathern bags to the mouth of the well. The moſt common crops are cotton, dohl, and the caſtor-oil plant, which latter riſes to the height of a large ſhrub, and ſhelters below its broad leaves the dohl and cotton ſhrub. Barley alone, or mixed with a kind of ſmall pea, is alſo a very common produce in this vicinity. Almoſt every common article of food is here very cheap: fowls from ſix to ten a rupee, and ducks at nearly the ſame price. Wheaten bread is much cheaper than in Britain; though it is more expenſive than any other farinaceous food, and therefore not generally uſed by the natives. Tennant's Indian Recreations, vol. ii.

DINAR, a mountain of Perſia.

DINARITUM, in *Ancient Geography*, a promontory of the iſle of Cyprus, now *Capo St. Andrea*; placed by M. D'Anville at the moſt eaſterly point of the iſland, near the iſles called *Clides*.

DINAS-MAWDDWY, or Dinasmouthy, in *Geography*, a townſhip and market town in the pariſh of Llany-Mowddû, or Mallwyd, in the hundred of Tallybont, Merionethſhire, Wales. It is ſeated on the river Dyfi, at the junction of three vallies, near a remarkable and romantic precipice called Craig-y-Dinas. Excepting the bold ſcenery of the neighbourhood, this place does not preſent any objects, or events, of curioſity or intereſt. It has a well ſupplied market on Fridays, and three annual fairs. Here is a good bridge over the river: the church is more than a mile from the town. "That this was a place of more conſequence than its preſent ſtate indicates cannot be denied; indeed the annals of Wales (*vide* Warrington) notice it as having been the ſeat of a chieftain; and its vicinity the ſcene of many a feat of valour and barbarity." (Evans's Tour through North Wales.) Mr. Evans infers that this town derived its name of Dinas from being a fortified palace of a prince; "and, as uſual, the diſtrict around was endowed with ſeveral privileges and exemptions, which continued under the title of ancient uſages, till reſtricted by the ſtatutes of Henry VIII.; when the laws of England were generouſly extended to the conquered country." This place is the capital of an extenſive lordſhip belonging to the Mytton family. According to Pennant, it is governed by "a mayor, aldermen, recorder, and ſeveral burgeſſes," the former tries criminals, and the recorder, in the abſence of the lord, hears and determines cauſes of debt, &c. not exceeding forty ſhillings. See Pennant's Tour in Wales, vol. ii.; and Evans's Tour through North Wales.

DINAW, a town of Poland, in the palatinate of Lemberg; 60 miles W.S.W. of Lemberg.

DINCKEL, a river of Germany, which runs into the Vechl, about ſeven miles N. from Nianhuys, in the county of Bentheim.—Alſo, a river of Germany, which runs into the Emmer, near Wobbel, in the county of Lippe.

DINDARI, in *Ancient Geography*, a people of Illyria, in Dalmatia.

DINDIGUL, in *Geography*, a town of India, in the Myſore country, capital of a diſtrict or circar, to which it gives name; 51 miles S. W. of Tritchinopoly, and 70 S. E. of Coimbore. N. lat. 10° 23′. E. long. 78° 6′.

DINDYMIS, in *Ancient Geography*, one of the names of Cyzica, ſituated in Aſia Minor, at the foot of mount Didymos, on the borders of the Propontide.

DINDYMOS, a mountain of Aſia Minor, in the peninſula of which Cyzica occupies the iſthmus. The mother of the gods had a temple in this mountain; it is thought to have been conſecrated by the Argonauts.

DINESTONS, in *Geography*, a town of America, in the ſtate of Pennſylvania; 25 miles E. of Pillſburg.

DING, in *Commerce*, a name which the Siameſe give in general to all ſorts of weights.

DINGAS, or *Bombay-barks*, in *Navigation*, are veſſels uſed at Bombay and places adjacent, which are ſometimes navigated

navigated by rowing with paddles. They have one maſt, one-third the length from the ſtern, which rakes much forward. On the maſt is hoiſted a ſail bent to a long yard, reſembling a ſettee-ſail: the laſh is made faſt to the head of the ſtern, and the ſheet to the keel of the maſt. Theſe veſſels never tack, but wear, in doing which they peck the yard againſt the maſt to ſhift the ſail; at the ſame time they paſs the ſheet before the maſt. Their rigging conſiſts of a pair of haliards, a bow-line, and brace. Their keels are very much hollowed upwards, to avoid wholly grounding on ſand-banks.

DINGE', in *Geography*, a town of France, in the department of the Ille and Vilaine and diſtrict of Dol; five leagues N. of Rennes.

DINGELFING, a ſmall town of Bavaria, ſituated on the river Iſer, in Lower Bavaria, between Landſhut and Straubing.

DINGELSTADT, a town of Germany, in the circle of the Lower Rhine, and county of Eichsfeld, on the Unſtrutt; 33 miles N. W. of Erfurt.

DINGLA, in *Ornithology*, the name given by Forſkal to the Larus *Cinerarius*.

DINGLE, in *Geography*, a market and poſt-town of the county of Kerry, Ireland: the Iriſh called it *Daingean-ni-Cuſhy; i e.* the faſtneſs or caſtle of Huſſey. In the reign of James I. a charter was granted to it under the name of *Dingle Cuſhy*, and it was ſince called *Dingle i-Couch*, though the addition is now ſeldom made. It is ſituated on a harbour towards the north ſide of Caſtlemain bay, which is but a quarter of a mile broad at the entrance, but grows wider, and in which veſſels are protected from every wind. Ships of a hundred tons may come up to the town. Before queen Elizabeth's reign, ſeveral Spaniſh merchants reſided at Dingle, who traded with the natives for fiſh and other kinds of proviſions. Several of the houſes were built in the Spaniſh faſhion, with ranges of ſtone balcony windows. Dingle, beſides its export of butter and other articles of proviſions, has a manufacture of coarſe linen, which takes its name from the town, and is much uſed for ſheeting. It was formerly a borough town, but has loſt its privilege of returning members to parliament by the union. It is 164 Iriſh miles S. W. from Dublin. Latitude 52° 8′ N.; longitude 10° 7′ W. from Greenwich. Smith's Kerry.

DINGMANS, a town of America, in the ſtate of Pennſylvania; 75 miles N. of Philadelphia.

DINGWALL, anciently written *Dingaval*, is the name of a pariſh in Roſs-ſhire, Scotland, ſeated near the weſtern ſhore of the Frith of Cromarty. This diſtrict conſiſts of an extenſive valley, and the ſides of ſeveral hills, the greater part of which is well cultivated. Oats, barley, peaſe, beans, and wheat, are the chief produce. About 100 acres are appropriated to ſown graſs, 200 to paſture, and 900 to plantations. In this pariſh is Dingwall, an ancient royal borough, which was created ſuch by king Alexander II. in 1226. Its charter of that date was confirmed by James IV. and its inhabitants empowered to elect a provoſt, two bailiffs, dean of guild, treaſurer, and ten counſellors. It joins with Kirkwall, Wick, Dornock, and Tain, in returning one member to parliament. Here was formerly a ſeat, or family manſion of the earls of Roſs, and parts of an ancient caſtellated building, with moat, &c. ſtill remain. Into the latter, the water was admitted at high tides, and the whole was adapted to protect the poſſeſſor in times of warfare. From foundations of houſes that have been diſcovered at ſome diſtance from the preſent town, and other ſimilar evidence, it is juſtly inferred that the ancient borough exceeded the preſent in extent. It is, however, certain, that modern improvements have rendered the preſent place more comfortable and convenient for human habitation, trade, and ſocial intercourſe. Near the church is an obeliſk, which riſes from a baſe of ſix ſquare feet, to the height of 57 feet. It was erected to diſtinguiſh the burial place of the Cromarty family. The population of the pariſh, in 1791, was 1379. Sinclair's Statiſtical Account of Scotland.

DINHABAH, in *Ancient Geography*, a city of Edom. Gen. xxxvi 32.

DINIA, Digne, a town of Gallia Narbonnenſis, and the capital of the Bodiontici, who lived near it. Its name is ſaid to be of Celtic original, derived from *din*, water, and *ia*, hot; ſo called from the thermal waters, at the diſtance of a quarter of a league from it. See Digne.

DINIÆ, a place of Aſia Minor, in Phrygia.

DININ, in *Geography*, a river of the county of Kilkenny, Ireland, which riſes in the mountainous diſtrict of Carlow weſt of the Barrow, and having received another ſtream from Caſtlecomer, joins the Nore a few miles above Kilkenny.

DINKELSBÜHL, or Dunkelspühl, in Latin *Tricollis*, *Zeacollis*, or *Zeapolis*, an ancient town of Germany, on the river Wernitz, ſeated on three hills, was formerly a free imperial city, which, in the diet of the empire, held the ſixteenth place on the bench of the imperial towns in Swabia; but at the peace of Luneville it was given to the king of Bavaria, as part of the indemnities to which he was entitled for his loſſes on the weſtern ſhore of the Rhine. The inhabitants and the magiſtrates are half Lutherans and half Roman Catholics.

DINKELSCHERBEN, a ſmall town of Germany, in the circle of Swabia, formerly belonging to the biſhopric of Augſburg.

DINKIRA, a country of Africa, a little inland of the Gold coaſt, W. of Inta or Aſſiento, ſix days' journey from Axim, and five from Elmina. On the eaſt it has Aſſiento, or, as ſome ſay, the intermediate country of Cabaſterra, on the weſt Adom, and on the north unknown regions extending to Barbary. This kingdom was formerly confined within narrow limits, and thinly inhabited; but the natural valour of the inhabitants rendered them formidable to all their neighbours, except thoſe of Achem and Aſſiento, who always maintained their ſuperiority by their numbers. When the roads are free and open, the Dinkineſe merchants, and the Acheneſe, frequent the markets of Axim, Elmina, Commendo, and Cape Coaſt; but when they are ſhut up, they direct their commercial attention to the more diſtant parts of the coaſt, and there occaſion a great afflux of wealth at the inferior factories. The gold of Dinkira is naturally fine, but artfully mixed with the Fetiche gold. As to the Acheneſe, they carry on a great trade with the natives, both of the coaſt and of the interior countries. Such is their eſtabliſhed reputation for honeſty and fair dealing, that the merchants of Commendo and Simpa give their gold the name of "alkanney chienka," on account of its purity and genuine qualities. They are fierce, bold, and warlike, ſo that they are no leſs dreaded than eſteemed by their neighbours. In travelling through the adjacent countries, they are hoſpitably entertained without expence. Their arms are darts, ſcymitars, and bucklers: and their language is a kind of compound of thoſe of the neighbouring countries with which they keep up an intercourſe, blended with many Portugueſe words borrowed by their anceſtors during their commerce with that nation.

DINNAGE. See Dunnage.

DINNER, the great meal, or that taken about the middle of the day.

The word is formed from the French *diſner*, which Du-Cange derives from the barbarous Latin *diſnare*. Henry Stephens

Stephens derives it from the Greek δινεω; and will have it wrote *dipner*. Menage deduces it from the Italian *definare*, to dine; and that from the Latin *definere*, to leave off work.

The grand Tartar, emperor of China, after he has dined, makes publication by his heralds, that he gives leave for all the other kings and potentates of the earth to go to dinner; as if they waited for his leave.

In the general, it is agreed to be the moſt ſalutary to make a ſpare ſupper, and to eat the more plentifully at dinner, eſpecially for tender, valetudinary people. This is the ſentiment of the Schola Salernitana.

"Ex magna cœna ſtomacho fit maxima pœna:
Ut ſis nocte levis, ſit tibi cœna brevis."

Yet Bernardinus Paternus, an eminent Italian phyſician, maintains the contrary, in a treatiſe expreſsly on the ſubject.

The Romans, we are aſſured, never minded dinner; but deferred their good cheer to the evening, which they made their grand meal.

DINO, in *Biography*, a celebrated Italian juriſt, was born about the middle of the 13th century. He ſtudied law at Bologna, and, in 1279, was invited to take the chair in that faculty at Piſtoia. Five years afterwards, he was appointed profeſſor of Bologna, with a handſome ſtipend. In 1296, he refuſed an invitation to Naples ſent by the king himſelf, and in the following year he removed to Rome, where Boniface VIII. employed him in compiling the ſixth book of decretals publiſhed in 1298. As a recompence for this labour, he hoped for the office of cardinal, and to enable him to hold it, he ſeparated from his wife, who entered into a convent, and enrolled himſelf in the clerical order: he did not ſucceed according to his expectations, and was obliged to reſume the profeſſorſhip. He died in 1303, leaving behind him ſeveral works of great authority. His commentary on the rules of law was ſo highly eſteemed, that it was recommended to be committed to memory. He wrote treatiſes on "The Pandects;" and "De Actionibus," and his authority was ſo great at Verona, that in difficult points it was decreed, that the opinion of Dino ſhould be deciſive. Moreri.

DINOCRATES, a famous architect of Macedonia, who flouriſhed about 330 years B. C. Having formed a variety of ſingular conceptions in the exerciſe of his profeſſion, he wiſhed to recommend himſelf to Alexander the Great, whilſt this conqueror was atchieving his military exploits. Accordingly he joined his army, and obtaining acceſs to Alexander, he propoſed to him a ſcheme for laying out mount Athos into the form of a man, having in his left hand the walls of a great city, and all the rivers of the mountain flowing through his right hand into the ſea. (See Athos.) Alexander, though ſeemingly pleaſed with the grand deſign, deferred the execution of it. Nevertheleſs, he took Dinocrates with him into Egypt, and employed him in marking out and building the city of Alexandria. He was alſo engaged by the Epheſians to ſuperintend the re-building of the temple of Diana. (See Diana.) The laſt great deſign which hiſtory aſcribes to him was that of erecting a temple to Arſinoe, queen of Ptolemy Philadelphus, at Alexandria, having a dome above it, on which was to be incloſed a magnet, in order to keep ſuſpended in the air an iron ſtatue of that queen. Ptolemy approved the deſign, and gave orders for its execution; but both the king and the architect died before the project could be accompliſhed.

DINOGETIA, in *Ancient Geography*, a town of Lower Mœſia, called *Dirigathia*, *Demigutia*, and *Dinogeſſia*.

DINOSTRATES, in *Biography*, a famous mathematician of the Platonic ſchool, the brother of Menechmus, and diſciple of Plato. Purſuing the ſteps of his brother, who amplified the theory of the conic ſections, Dinoſtrates is ſaid to have made many geometrical diſcoveries; but he is particularly diſtinguiſhed as the inventor of the *quadratrix*, which ſee. Montucla, however, obſerves (Hiſt. Mathem. v. i. p. 181.) that there is ſome reaſon for aſcribing the original invention of this curve to Hippias of Elæa, an ingenious philoſopher and geometer, contemporary with Socrates.

DINSLAKEN, in *Geography*, a town of Germany, in the circle of Weſtphalia, and duchy of Cleves; 23 miles S.E. of Cleves.

DINUS, in *Ancient Geography*, a port of Aſia Minor, in Lycia.

DINUS, in *Medicine*, according to ſome, is the name of a diſeaſe, called more uſually vertigo.

DINWIDDIE, in *Geography*, a county of America, in Virginia, S. of Appamatox river, which divides it from Cheſterfield. It is about 30 miles long, and 20 broad, and its chief town is Peterſburg. It contains 4987 free inhabitants, and 6866 ſlaves.

DIO, in *Biography*, a celebrated Stoic, who lived in the time of Nero, was a native of Pruſa, in Bithynia, and denominated, on account of his eloquence, Chryſoſtom. Under Nero and Veſpaſian he maintained the profeſſion of a Sophiſt: and frequently inveighed, in a declamatory and luxuriant ſtyle, againſt the moſt illuſtrious poets and philoſophers of antiquity; which obliged him to leave Rome, and withdraw to Egypt. He then aſſumed the character of a Stoic philoſopher; embelliſhing, however, his philoſophical diſcourſes, that treated of moral topics, with the graces of eloquence. As his character correſponded to his principles of virtue, he was a bold cenſor of vice, and ſpared no individual on account of his rank. By his freedom of ſpeech he offended Domitian, and being obliged to become a voluntary exile in Thrace, he lived in great poverty, and ſupported himſelf by private labour. After the death of this emperor, he returned to Rome, and for ſome time remained concealed; but when he found the ſoldiers inclined to ſedition, he brought to their recollection Dio the orator and philoſopher, by haranguing them in a ſtrain of manly eloquence, which ſoon ſubdued the tumult. He was admitted into the confidence of Nerva and Trajan, and diſtinguiſhed by the former with tokens of favour. He lived to old age, but the time of his death cannot be aſcertained. His "Orations" are ſtill extant, from which we may infer that he was a man of ſound judgment and lively fancy, and that he blended in his ſtyle the qualities of animation and ſweetneſs. Brucker's Hiſt. Phil. by Enfield, vol. ii.

DIOCÆSAREA, in *Ancient Geography*, a town of Aſia, placed by Pliny and Ptolemy in a country of Cappadocia. —Alſo, a town of Aſia Minor ſituated on the river Calycadnus in the weſtern part of Cilicia. Under the Philips, it was ſignalized by the title of metropolis. See Sephoris.

DIOCALLIA, in *Botany*, a name by which Apuleius and ſome other authors have called the common ſweet chamomile.

DIOCESE, or Diocess, the circuit, or extent, of the juriſdiction of a biſhop. See Bishop.

The word is formed from the Greek διοικησις, *government*, *adminiſtration*, formed of διοικεω, which the ancient gloſſaries render *adminiſtro*, *moderor*, *ordino*: hence διοικησις της πολεως, the *adminiſtration*, or *government of a city*.

Diocese is alſo uſed, in *Ancient Authors*, &c. for the province of a metropolitan. See Province and Metropolis.

Diocæſis, Διοικησις, was originally a civil government, or prefecture, compoſed of divers provinces.

The

The firſt diviſion of the empire into dioceſes is ordinarily aſcribed to Conſtantine, who diſtributed the whole Roman ſtate into four, *viz.* the dioceſe of Italy, the dioceſe of Illyriæ, that of the Eaſt, and that of Africa. And yet, long time before Conſtantine, Strabo, who wrote under Tiberius, takes notice, (lib. xiii. p. 432.) that the Romans had divided Aſia into dioceſes, and complains of the confuſion ſuch a diviſion occaſioned in geography; Aſia being no longer divided by people, but by dioceſes, each whereof had a tribunal, or court, where juſtice was adminiſtered. Conſtantine, then, was only the inſtitutor of thoſe large dioceſes, which comprehended ſeveral metropoles and governments; the former dioceſes only comprehending one juriſdiction, or diſtrict, or the country that had reſort to one judge, as appears from this paſſage in Strabo, and, before Strabo, from Cicero himſelf, (lib. iii. Epiſt. ad Famil. Ep. 9. and lib. xiii. Ep. 67.) who, when proconſul of Cilicia, often mentions the dioceſes that were annexed to his government: and alſo in his command of Capua, he calls himſelf the "episcopus" of the Campanian coaſt; which ſhews, that theſe names, which were afterwards appropriated in the Chriſtian church to characters and powers eccleſiaſtical, carried with them in their original uſe the notion of a real authority and juriſdiction. Thus, at firſt, a province included divers dioceſes, and afterwards a dioceſe came to compriſe divers provinces. In after-times the Roman empire became divided into thirteen dioceſes, or prefectures; though, including Rome, and the ſub-urbicary regions, there were fourteen. Theſe fourteen dioceſes comprehended a hundred and twenty provinces; each province had a pro-conſul, who reſided in the capital, or metropolis; and each dioceſe of the empire had a conſul, who reſided in the principal city of the diſtrict.

On this civil conſtitution the eccleſiaſtical one was afterwards regulated; each dioceſe had an eccleſiaſtical vicar, or primate, who judged finally of all the concerns of the church within his territory.

At preſent there is ſome farther alteration; for dioceſe does not now ſignify an aſſemblage of divers provinces, but is limited to a ſingle province, under a metropolitan, or even to the ſingle juriſdiction of a biſhop.

England, with regard to its eccleſiaſtical ſtate, is divided into two provinces, *viz.* Canterbury and York; the former province contains twenty-one dioceſes, and the latter three, beſides the biſhopric of the iſle of Man, which was annexed to the province of York by Henry VIII. Every dioceſe is divided into archdeaconries, of which there are ſixty in all; and each archdeaconry into rural deaneries; and every deanery into pariſhes.

The bounds of dioceſes are to be determined by witneſſes and records, but more particularly by the adminiſtration of divine offices. To which purpoſe there are two rules in the canon law; in one caſe, upon a diſpute between two biſhops on this head, the direction is, that they proceed in the buſineſs by ancient books and writings, and alſo by witneſſes, reputation, and other ſufficient proof; in the other caſe, where the queſtion was, by whom a church built upon the confines of two dioceſes ſhould be conſecrated, the rule laid down is, that it ſhould be conſecrated by the biſhop of that city, who, before it was founded, baptized the inhabitants, and adminiſtered to them other divine offices. The juriſdiction of the *city* is not included in the name of *dioceſe*, according to the canon law; and, therefore, in citations in general viſitations, directed to the clergy, it is ordered to cite the clergy of the *city* and *dioceſe*. A biſhop may perform divine offices, and uſe his epiſcopal habit, in the dioceſe of another, without leave, but may not perform there any act of juriſdiction, without permiſſion. A clergyman dwelling in one dioceſe, and beneficed in another, may, in different reſpects, be puniſhed in both; that is, the biſhop, in whoſe dioceſe he dwells, may proſecute him; but the ſentence, ſo far as it affects his benefice, muſt be carried into execution by the other biſhop. Gibſon, 133, 134.

Gul. Brito affirms dioceſe to be properly the territory and extent of a baptiſmal, or parochial church; whence divers authors uſe the word to ſignify a ſimple pariſh.

It is obſerved by lord King (Conſt. Diſcipl. &c. of the Primitive Church, p. 15.) that the ancient dioceſes are never ſaid to contain churches in the plural, but only a church in the ſingular. (See CHURCH.) As for the word dioceſe, by which the biſhop's flock is now uſually expreſſed, he ſays that he does not remember to have found it uſed in this ſenſe by any of the ancients; but they frequently denominated the biſhop's cure by the term pariſh. Thus, in the ſynodical epiſtles of Irenæus to pope Victor, the biſhoprics of Aſia are twice called pariſhes; and in Euſebius's Eccleſiaſtical Hiſtory the word is ſo applied in ſeveral hundred places. Accordingly, we often read of the biſhops of the pariſh of Alexandria, of Epheſus, of Corinth, of Athens, and of Carthage; and alſo of the biſhops of ſeveral other churches. This ingenious and impartial writer alleges ſeveral conſiderations, in order to ſhew, that the biſhop's dioceſe did not exceed the bounds of a modern pariſh, and that it was, really as well as nominally, the ſame. All the people of a dioceſe met all together every Sunday, in one place, to celebrate divine ſervice; and, therefore, the biſhop's church could not have been larger than our pariſhes, or elſe, it would have been impoſſible that the members of it ſhould have been conſtantly aſſembled together in one place. Further, the biſhop had but one altar, or communion-table, in his whole dioceſe, at which his whole flock received the ſacrament from him. Beſides, the other ſacrament of baptiſm was generally adminiſtered by the biſhops alone within their reſpective dioceſes; and, therefore, it is not probable, nor, indeed, ſcarcely poſſible, that their dioceſes were extended beyond the bulk of ſingle congregations. Moreover, the church's charity was depoſited with the biſhop; conſequently, that dioceſe could not be very large, where the biſhop perſonally relieved and ſuccoured all the poor that reſided in it. Again, all the people of a dioceſe were preſent at church-cenſures: and no offenders were reſtored again to the peace of the church, without the knowledge and conſent of the whole dioceſe. When the biſhop of a church was dead, all the people of that church met together in one place to chooſe a new biſhop. At the ordinations of the clergy, the whole body of the people were preſent. Public letters from one church to another were read before the whole dioceſe: and the whole dioceſe of the biſhop met together to manage church-affairs. From all theſe conſiderations, ſupported by citations from ancient writers, the author infers that a dioceſe, in the primitive ages of Chriſtianity, could not be larger than a ſingle congregation. This reaſoning is further confirmed by an inquiry into the real ſize of thoſe biſhoprics concerning which we have any notice on ancient records, whence it appears that the largeſt of them were not greater than our particular congregations. Accordingly, Ignatius gives ſuch an account of the biſhoprics of Smyrna, Epheſus, Magneſia, Philadelphia, and Trallium, as plainly proves that they were ſo many ſingle congregations. Upon the whole it is concluded, that the greateſt biſhoprics in the world, even in the third century, were no more than ſo many ſingle congregations. The four largeſt dioceſes, which ſubſiſted in thoſe days, were Antioch, Rome, Carthage, and Alexandria; the

the three former of which, during three centuries after Chriſt, never branched themſelves into ſeparate congregations; though the latter did, on account of local circumſtances, which rendered it inconvenient for all the members of this dioceſe to aſſemble, at the ſtated times of worſhip, in one and the ſame place. This ſeparation, however, was not introduced till the third century, and was peculiar to the biſhopric of Alexandria.

DIOCESE, *Aſiatic*. See ASIATIC *Dioceſe*.

DIOCLEA, in *Ancient Geography*, a town of Illyria, in Dalmatia, called by Ptolemy Doclea, the native place of Diocleſian. This town is now ruined; it was not far from Narona, now Narenza.

DIOCLEIA, Διοκλεια, in *Antiquity*, a ſolemnity kept in the ſpring at Megara, in memory of the Athenian hero Diocles, who died in the defence of the youth he loved. Pott. Arcæol. Græc. lib. ii. cap. 20.

DIOCLES, in *Biography*, a mathematician who flouriſhed about the fourth century; he invented the curve line denominated the CISSOID of Diocles, and for this his name is chiefly celebrated. It is reckoned by ſir Iſaac Newton among the defective hyperbolas, and is uſed for finding two mean proportionals between two other given lines. Moreri.

DIOCLESIAN, or DIOCLETIAN, in *Biography*, a Roman emperor, was born A.D. 245, at Diocea, or Doclea, in Dalmatia, from which town he derived his firſt name, which was probably Docles, afterwards lengthened to the Grecian harmony of Diocles, which was alſo the name of his mother; and, at length, after his acceſſion to the empire, to the Roman majeſty of Diocletianus or Diocleſianus. He likewiſe aſſumed the patrician name of Valerius. The parents of Diocleſian had been ſlaves in the houſe of Anulinus, a Roman ſenator; but it is probable that his father obtained the freedom of the family, and that he ſoon acquired an office of ſcribe, or regiſter, which was commonly exerciſed by perſons of his condition. Victor the Younger (Epit. p. 542.) reports, that he was himſelf, in his youth, ſlave to the ſenator Anulinus, who gave him his liberty. At an early age he embraced the profeſſion of arms, in which he muſt have excelled, as he is reckoned among the good generals formed under the diſcipline of Probus, and as he raiſed himſelf to the firſt military employments. At the commencement of his career, and whilſt he occupied ſome inferior poſt, it is ſaid that a Druid woman, in whoſe houſe he lodged, upbraided him with covetouſneſs; to whom he jocoſely replied, "I ſhall be more generous when I am emperor." "You are joking," replied the Druideſs; "but I tell you, in good earneſt, that you will attain the empire after you have killed a boar." This circumſtance is ſaid to have occurred in the city of Tongres, in the preſent biſhopric of Liege. In recompence of his ſervices under Probus, he was promoted to the government of Mœſia, and having diſtinguiſhed himſelf in the expedition of Carus againſt the Perſians, he was advanced by that prince to the conſulſhip. At the time of Numerian's death, he held the honourable and important office of commander of the guards of the palace, or, as this office was called, "count of the domeſtics."

On the 17th of September, A.D. 284, he was elevated to the imperial throne by the unanimous voice of the army. As ſoon as he was proclaimed, he aſcended the tribunal, and, after having harangued the ſoldiers, and ſolemnly declared, upon oath, that he had not been acceſſary or privy to the death of Numerian, he cauſed Aper to be ſeized, reproached him in bitter terms with the murder of his prince and ſon-in-law; and then deſcending from the tribunal, plunged his ſword in his breaſt; ſaying, "You ſhall have the honour, Aper, to fall by an illuſtrious hand." Thus, it is ſaid, he fulfilled the prediction of the Druideſs, the word *Aper* ſignifying a *boar*; and therefore, on ſeeing Aper falling, he cried out, "I have, at length, killed the fatal boar!" The epocha of Diocleſian's proclamation at Chalcedon forms a new era, for an account of which ſee *Diocleſian* EPOCHA.

Diocleſian made his public entry into Nicomedia on the 27th of September of this year, 284. In the year 285, he commanded the troops that had lately returned from the Perſian war in a conteſt with the infamous Carinus, brother of Numerian, who endeavoured to ſupport his legal title to the empire. On this occaſion the troops under his command ſuffered a defeat, and Diocleſian deſpaired both of the purple and of life. But the advantage which Carinus had obtained by the valour of his ſoldiers, he quickly loſt by the infidelity of his officers. A tribune, whoſe wife he had ſeduced, ſeized the opportunity of revenge, and, by a ſingle blow, extinguiſhed civil diſcord in the blood of the adulterer. After the advantage thus gained, his conduct was ſingularly mild and honourable. He not only pardoned all who had borne arms againſt him, whom he juſtly thought not blameable for having ſerved a prince whoſe title was ſo legitimate as that of Carinus; but he alſo continued in their poſts and dignities thoſe who had been promoted by his enemy. Motives of policy might, indeed, on this occaſion, aſſiſt the humanity of Diocleſian. The diſcerning judgment of Aurelian, of Probus, and of Carus, had filled the ſeveral departments of the ſtate and army with officers of approved merit, whoſe removal would have injured the public ſervice, without promoting the intereſt of the ſucceſſor. Such a conduct, however, diſplayed to the Roman world the faireſt proſpect of the new reign; and the emperor affected to confirm this favourable prepoſſeſſion, by declaring that, among all the virtues of his predeceſſors, he was the moſt ambitious of imitating the humane philoſophy of Marcus Antoninus. This is the account of Aurelius Victor; but Eutropius aſſerts that he was betrayed by his own army, and killed by Diocleſian.

When Diocleſian found himſelf, by the death of his rival, ſole maſter of the empire, he marched to Rome, and, being acknowledged there, he ſpent the winter at Nicomedia. In the mean while he viſited Germany, where he gained ſeveral advantages over the Alemanni, who had made an irruption into Gaul. In the ſame year his generals fought with ſucceſs againſt the inhabitants of Britain, who had attempted to ſhake off the yoke. On account of theſe victories he aſſumed the appellations of Germanicus and Britannicus, which we find on medals. From Germany he returned through Illyricum into the eaſt; for he was at Sirmium on the firſt day of the following year, and at Nicomedia on the 21ſt of January. In the courſe of this year, *viz.*, April 1, 286, he took Maximian, ſtyled on the ancient coins M. Aurelius Valerius Maximianus, for his colleague and partner in the empire. (See MAXIMIAN.) On Maximian he beſtowed at firſt the title of Cæſar, and afterwards that of Auguſtus. The motive that induced him to make this appointment ſeems to have been an apprehenſion that the numerous enemies with whom he had to contend, would be too powerful for him without the aſſiſtance of a perſon of Maximian's military talents and bold enterprizing ſpirit; for Diocleſian himſelf was leſs a warrior than a ſtateſman, nor does he ſeem to have poſſeſſed the daring and generous ſpirit of a hero, who courts danger and fame, diſdains artifice, and boldly challenges the allegiance of his equals. Maximian he had long known; he was well acquainted with his ruling diſpoſition and general character; his fidelity and attachment he had long experienced; and he was ſufficiently aſſured that he would ſerve the purpoſes for which he was appointed, and,

and, at the ſame time, aſſume no independent authority and command. Of his vices alſo Diocleſian was well apprized, and he knew how to render them uſeful. Inſenſible to pity, and fearleſs of conſequences, he was the ready inſtrument of every act of cruelty which the policy of that artful prince might at once ſuggeſt and diſdain. As ſoon as a bloody ſacrifice had been offered to prudence or revenge, Diocleſian, by his ſeaſonable interceſſion, ſaved the remaining few, whom he had never deſigned to puniſh, cenſured the ſeverity of his ſtern colleague, and enjoyed the compariſon of a golden and an iron age, which are univerſally applied to their oppoſite maxims of government. Notwithſtanding the difference of their characters, the two emperors maintained, on the throne, that friendſhip which they had contracted in a private ſtation. The haughty turbulent ſpirit of Maximian, ſo fatal afterwards to himſelf and the public peace, was accuſtomed to reſpect the genius of Diocleſian, and confeſſed the aſcendant of reaſon over brutal violence. From a motive either of pride or ſuperſtition, the two emperors aſſumed the titles, the one of Jovius, the other of Herculius: though Crevier ſays, that theſe were names afterwards conferred on the two Cæſars, Galerius and Conſtantius.

Diocleſian, after having aſſociated Maximian, prepared to march againſt the Perſians, and charged his colleague with the war in the weſt, who juſtified the choice that had been made by the ſignal ſucceſs of his arms. Diocleſian himſelf, though no great warrior, was not inactive. By the terror of his name he induced the king of Perſia to ſue for peace; and his panegyriſts mention the victories which he gained over the Alemanni in Rhætia, and over the Sarmatians, whence he was called Sarmaticus, the Juthongi, the Quadi, the Carpians, and the Goths, in Pannonia and the neighbouring countries. After theſe exploits of the two emperors, for which they obtained a triumph, they had an interview at Milan, A.D. 290. In order to repair thither, they croſſed, in the midſt of winter, one of them the Julian Alps in his way from Pannonia, and the other the Cottian Alps, which are thoſe neareſt Gaul. What was the motive of this interview hiſtory has not recorded: but if it merely ſerved to exhibit the cordial union that ſubſiſted between them, it muſt greatly contribute to maintain peace and tranquillity in the empire. However, new dangers preſented themſelves, and therefore the two emperors determined to ſtrengthen their power and intereſt, by conferring on two generals of approved merit, with the inferior title of *Cæſars*, an equal ſhare of the ſovereign authority. This event took place, A.D. 292. Galerius, ſurnamed Armentarius, from his original profeſſion of a herdſman, and Conſtantius, who from his pale complexion had acquired the denomination of Chlorus, were the two perſons inveſted with the ſecond honours of the imperial purple. The two emperors, in order the better to cement the union between them and their Cæſars, obliged them to repudiate their wives, and ally themſelves to the imperial families. Accordingly, Conſtantius married Theodora, daughter-in-law to Maximian; and Galerius eſpouſed Valeria, the daughter of Diocleſian. Theſe four princes diſtributed among themſelves the wide extent of the Roman empire. The defence of Gaul, Spain, and Britain, was entruſted to Conſtantius; Galerius was ſtationed on the banks of the Danube, as the ſafeguard of the Illyrian provinces; Italy and Africa were conſidered as the department of Maximian; and for his peculiar portion, Diocleſian reſerved Thrace, Egypt, and the rich countries of Aſia. Every one was ſovereign within his own juriſdiction, but their united authority extended over the whole monarchy; and each of them was prepared to aſſiſt his colleagues with his counſels or preſence. After the adoption of the two Cæſars, the emperors themſelves, retiring to a leſs laborious ſcene of action, devolved on their adopted ſons the defence of the Danube and of the Rhine. The vigilant Galerius was never reduced to the neceſſity of vanquiſhing an army of barbarians on the Roman territory. The brave and active Conſtantius delivered Gaul from a very furious inroad of the Alemanni; and his victories of Langres and Vindoniſſa appear to have been actions of conſiderable danger and merit. In the diſpoſal of the captive barbarians, Diocleſian and his aſſociates imitated the conduct of Probus, and diſtributed them among the provincials, and thoſe diſtricts were aſſigned them, which had been depopulated by the calamities of war. They were uſefully employed as ſhepherds and huſbandmen, but were denied the exerciſe of arms, except when it was found expedient to enrol them in the military ſervice. While the Cæſars were exerciſing their valour on the banks of the Rhine and Danube, the emperors were called to the ſouthern confines of the Roman world. From the Nile to mount Atlas, Africa was in arms. A confederacy of five Mooriſh nations, called Quinque-gentiani, iſſued from their deſerts to invade the peaceful provinces. Julian had aſſumed the purple at Carthage. Achilleus at Alexandria; and the Blemmyes, ſcattered between the iſland of Meroe and the Red ſea, continued their incurſions into Upper Egypt. Although we have no particular detail of the exploits of Maximian in weſtern Africa, we know in general that he vanquiſhed the fierceſt barbarians of Mauritania. Diocleſian undertook the ſiege of Alexandria, occupied by Achilleus, and having proſecuted it for eight months, the city ſubmitted, but experienced the full extent of his ſeverity. Many thouſands of the citizens periſhed in a promiſcuous ſlaughter. The fate of Buſiris and Coptos was ſtill more melancholy than that of Alexandria. Whilſt Diocleſian vigorouſly chaſtiſed the paſt crimes of the Egyptians, he provided for their future welfare by many wiſe regulations, which were confirmed and enforced under the ſucceeding reigns. He alſo by an edict ſuppreſſed all books of alchemy which the Arabs, by the conqueſt of Egypt, had been the means of diffuſing over the globe. The reduction of Egypt was immediately followed by the Perſian war. It commenced A.D. 296; at which time Diocleſian fixed his ſtation in the city of Antioch, from whence he prepared and directed the military operations. Galerius had the charge of the Roman legions; but after two battles of various and doubtful ſucceſs, he was totally defeated in a third engagement, the diſaſter of which was attributed to his own raſhneſs in preſuming, with an inconſiderable body of troops, to attack the innumerable hoſt of the Perſians. When he returned to Antioch, Diocleſian received him, not with the uſual expreſſions of friendſhip, but with the indignation of an offended ſovereign. The haughtieſt of men, clothed in his purple, but humbled by the ſenſe of his misfortune and diſgrace, was obliged to follow the emperor's chariot above a mile on foot, and to exhibit, before the whole court, the ſpectacle of his diſgrace. Diocleſian, however, having indulged his reſentment, and aſſerted the majeſty of ſupreme power, allowed Galerius, at his earneſt entreaty, to retrieve his own honour, as well as that of the Roman name. A ſtrong force was provided for him, and at the head of a choſen army of 25,000 men, he again paſſed the Euphrates, and by his circumſpection and valour obtained a complete victory over the Perſian army. In the general confuſion and carnage, Narſes, the wounded monarch, fled towards the deſerts of Media, and left behind him an immenſe booty to the conqueror. Several of his wives, his ſiſters, and children, were in the number of the captives, who were honourably protected from violence and rapine, con-

veyed to a place of ſafety, and treated with every mark of tenderneſs and reſpect that was due from a generous army to their age, their ſex, and their royal dignity. The emperor Diocleſian, who had aſſembled in Syria a ſtrong army of obſervation, and was anxiouſly waiting the event, as ſoon as he received intelligence of the victory, advanced towards the frontier, in order, by his preſence and counſels, to moderate the pride of Galerius. The interview of the Roman princes at Niſibis was accompanied with every expreſſion of reſpect on one ſide, and of eſteem on the other. Here they ſoon afterwards gave audiences to the ambaſſador of the great king. In the conference that enſued, Galerius manifeſted the fierceneſs of his paſſion, as well as his deference to the ſuperior wiſdom and authority of Diocleſian. The ambition of the former graſped at the conqueſt of the eaſt, and had propoſed to reduce Perſia into the ſtate of a province. The prudence of the latter, who adhered to the moderate policy of Auguſtus and the Antonines, embraced the favourable opportunity of terminating a ſucceſsful war by an honourable and advantageous peace. Accordingly, after the adjuſtment of ſome previous circumſtances, a ſolemn peace was concluded and ratified between the two nations.

The conditions of this peace were, that Narſes ſhould cede to the Romans five provinces beyond the Tigris, *viz.* Intilene, Zabdicene, Arzanene, Sophene, and Carduene, which by their ſituation formed a very uſeful barrier, and whoſe natural ſtrength was ſoon improved by art and military ſkill;—that the Aboras, or as Xenophon calls it, the Araxes, ſhould be the boundary between the two monarchies: and not the Tigris, as ſome authors have ſtated in conſequence of an error of the geographer Ptolemy, who removed the poſition of Singara from the Aboras to the Tigris; by this article of the treaty Meſopotamia, which had been the object of many wars, was ceded to the empire, and the Perſians renounced all pretenſions to that great province:—that the limits of Armenia ſhould be extended to the fortreſs of Sintha or Zintha, on the confines of Media:—that the king of Iberia ſhould receive his crown from the Roman emperors, and be no longer dependent on the kings of Perſia:—and that Niſibis ſhould be a common emporium or mart of commerce between the two empires; but to this latter article Narſes objected, whilſt he complied with all the reſt. The wives and children of the Perſian king were reſtored to him; but the other priſoners were retained by Diocleſian to grace his ſubſequent triumph. This peace was very advantageous to the Romans, and laſted 40 years, from the year 297, when the war terminated, to the year 337, when Conſtantine, provoked by Sapor, who wanted to withdraw the five provinces ceded to Diocleſian, would have made war againſt the Perſians, if he had not been prevented by death. Galerius's victory over Narſes, though glorious to the Roman empire, was fatal to Diocleſian. It ſwelled the pride of the conqueror, who aſſumed the pompous titles of Perſicus, Armeniacus, Adiabenicus, and Mediacus: and diſdaining a mortal origin, ſtyled himſelf the ſon of Mars. Although he was treated with high diſtinction by his adoptive father and emperor, he became weary of holding only the ſecond rank. "Always Cæſar," ſaid he, "How long will it be till I ſhall be nothing but Cæſar?" At length, gaining an aſcendant over Diocleſian, he prevailed on him to perſecute the Chriſtians, and reduced him to the neceſſity of abdicating the empire. During the five years that elapſed between the peace concluded with the Perſians, and the perſecution ordered againſt the Chriſtians, Diocleſian employed his time chiefly in providing for the internal welfare of the empire, and in ſecuring its frontiers by caſtles built upon the Rhine, the Danube, and the Euphrates. Ammianus Marcellinus particularly mentions Cercuſium, or Circeſium, in Meſopotamia, a frontier town, at the confluence of the Aboras and the Euphrates, which he ſtrongly fortified, and thus rendered an important poſt. It was alſo, during this ſame interval of tranquillity, that Diocleſian erected his magnificent and expenſive buildings at Nicomedia, and that baths were conſtructed by Maximian at Carthage. In the year 302, a great ſcarcity prevailed in moſt provinces of the empire; and Procopius ſays, that Diocleſian ordered two millions of buſhels of corn to be yearly diſtributed among the inhabitants of Antioch, and a ſimilar diſtribution was made in the city of Alexandria. Galerius paſſed the winter of this year with Diocleſian in the palace of Nicomedia; and the fate of Chriſtianity became the object of their ſecret conſultations. Galerius had been brought up in hatred of the Chriſtian name by his mother, a woman extremely ſuperſtitious, who, offering frequent ſacrifices in her village to the pretended deities of the mountains, had taken great offence at the Chriſtians, becauſe they refuſed to partake of the repaſts which ſhe gave at the ſame time, and becauſe they faſted and prayed whilſt ſhe celebrated feaſts of joy with the inhabitants of the place. Galerius, no leſs ſuperſtitious than his mother, and full of the prejudices which he had imbibed from her inſtruction, embraced the firſt favourable opportunity of converſing with the emperor, and diſpoſing him to concur in meaſures of perſecution. A circumſtance is ſaid to have occurred which promoted the views of Galerius. As the emperor was offering ſacrifices in order to aſcertain the will of the gods, by inſpecting the entrails of animals, concerning the events of futurity, the Chriſtians diſturbed the prieſts in the performance of their office; and as theſe miniſters of ſuperſtition and deluſion were unable to give the emperor the ſatisfaction which he deſired, they alleged the interference of profane perſons, as they called Chriſtians, and charged upon them the failure of their ſucceſs. The emperor was incenſed; and puniſhed both the officers of the palace and army, who would not join in his ſacrifices. Galerius took the advantage of this circumſtance; and in his converſation with Diocleſian uſed a variety of arguments to induce him to commence and afterwards to extend the horrid work of perſecution. The emperor himſelf was rather inclined to meaſures of lenity, and though he readily conſented to exclude the Chriſtians from holding any employments in the houſehold or the army, he urged in the ſtrongeſt terms the danger, as well as cruelty, of ſhedding the blood of thoſe deluded fanatics, as he ſeemed to regard them. At length, however, Galerius prevailed; a council was ſummoned, conſiſting of the principal perſons in the civil and military departments of the ſtate: violent meaſures were recommended; and Diocleſian yielded and acquieſced. On the 23d of February, A.D. 303, the perſecution commenced by the demolition of the church of Nicomedia; and on the next day the general edict was publiſhed; and it was enacted, that the churches of the Chriſtians, in all the provinces of the empire, ſhould be demoliſhed to their foundations; and the puniſhment of death was denounced againſt all who ſhould preſume to hold any ſecret aſſemblies for the purpoſe of religious worſhip. Their ſacred books were commanded to be publicly burnt; the property of the church was confiſcated: and in order to induce individuals, who were found to be obſtinate in their attachment to their Chriſtian profeſſion, to abandon it, and to prevent others from rejecting the religion of nature, of Rome, and of their anceſtors, violent meaſures of various kinds were purſued. Perſons of a liberal birth were declared incapable of holding any honours or employments; ſlaves were for ever deprived

of

of the hopes of freedom, and the whole body of the people were put out of the protection of the law. The judges were authoriſed to hear and to determine every action that was brought againſt the Chriſtians; but the Chriſtians were not permitted to complain of any injury which they themſelves had ſuffered, and thus they were expoſed to the ſeverity, whilſt they were excluded from the benefits of public juſtice. This edict was ſcarcely exhibited to public view, in the moſt conſpicuous place of Nicomedia, before it was torn down by the hands of a Chriſtian, who is ſaid, at the ſame time, to have expreſſed, by the bittereſt invectives, his contempt as well as abhorrence of ſuch tyrannical governors. For this act of contumacy he was burnt, or rather roaſted by a ſlow fire; but his executioners were unable, by this refinement of cruelty, to ſubdue his patience, or to make him to alter the ſteady and inſulting ſmile which, in his dying agonies, he ſtill exhibited in his countenance. Within 15 days after the firſt edict was iſſued, the palace of Nicomedia, and even the bed-chamber of Dioclesian, were twice in flames; and though they were extinguiſhed without any material damage, the repetition of the fire was conſidered as a convincing proof, that it was not the effect of chance or negligence. Euſebius writes, that he could never learn how that accident had happened. Conſtantine, who was on the ſpot, aſcribes it to lightning: and Lactantius aſſures us, that Galerius cauſed the palace to be privately ſet on fire, that he might accuſe the Chriſtians, and by that calumny incenſe Dioclesian ſtill more againſt them. It did produce this effect; for Dioclesian, aſcribing it to the Chriſtians, reſolved to puniſh them with the utmoſt ſeverity: and Galerius, the more to exaſperate him againſt them, withdrew from Nicomedia the ſame day, pretending that he was afraid of being burnt alive by thoſe incendiaries. For a further account of this perſecution, which was extremely grievous, and which laſted ten years; ſee PERSECUTION.

The arduous work of reſcuing the diſtreſſed empire from tyrants and barbarians having been completely atchieved, and Dioclesian having entered into the twentieth year of his reign, A. D. 303, he celebrated that memorable era, as well as the ſucceſs of his arms, by the pomp of a Roman triumph. Maximian, the only equal partner of his power, was his only companion in the glory of that day. This triumph, which was dignified and ſplendid, was the laſt that Rome ever beheld; for ſoon after this period, the emperors ceaſed to vanquiſh, and Rome ceaſed to be a capital of the empire. Whilſt Maximian fixed his reſidence at Milan, Dioclesian employed his leiſure, and the wealth of the Eaſt, in embelliſhing Nicomedia, a city placed on the verge of Europe and Aſia, and almoſt at an equal diſtance between the Danube and the Euphrates; which, in proceſs of time, was inferior only to Rome, Alexandria, and Antioch, in extent or populouſneſs. As Dioclesian had framed a new ſyſtem of imperial government, which was afterwards completed by the family of Conſtantine, he adopted every meaſure that tended to debaſe Rome, and the Roman ſenate. Civil magiſtracies, and their modeſt titles of conſul, proconſul, cenſor, and tribune, were laid aſide, and imperial dignity and correſponding titles were aſſumed. Even the attributes, or at leaſt the titles of the divinity, were uſurped by Dioclesian and Maximian, who tranſmitted them to a ſucceſſion of Chriſtian emperors. Dioclesian introduced the ſtately magnificence of the Perſian court; he aſſumed the diadem, though deteſted by the Romans, as the odious enſign of royalty; and his ſumptuous robes, and thoſe of his ſucceſſors, were of ſilk and gold; and it is remarked with indignation, that even their ſhoes were ſtudded with the moſt precious gems. Acceſs to their ſacred perſons was every day rendered more difficult, by the inſtitution of new forms and ceremonies. The avenues of the palace were ſtrictly guarded; and the interior apartments were entruſted to the jealous vigilance of eunuchs, the increaſe of whoſe number and influence was the moſt infallible ſymptom of the progreſs of deſpotiſm. When a ſubject was at length introduced into the imperial preſence, he was obliged, whatever might be his rank, to fall proſtrate on the ground, and to adore, according to the Eaſtern faſhion, the divinity of his lord and maſter. The firſt principle of the new ſyſtem inſtituted by Dioclesian, was oſtentation, and the ſecond diviſion; for he divided the empire, the provinces, and every branch of the civil, as well as military adminiſtration; and this principle of diviſion, in the courſe of a few years, occaſioned the perpetual ſeparation of the eaſtern and weſtern empires under the ſyſtem introduced by Dioclesian. The number of miniſters, of magiſtrates, of officers, and of ſervants, who filled the different departments of ſtate, was multiplied beyond all former example; and of courſe his ſyſtem was accompanied with a more expenſive eſtabliſhment, and conſequently an increaſe of taxes, and the oppreſſion of the people. Dioclesian, after this ceremony of his triumph, left Italy, and commenced his progreſs towards the circuit of his Illyrian provinces. The fatigue of the journey, and the inclemency of the weather, occaſioned a diſorder, which, before he arrived at Nicomedia, towards the end of the ſummer, A.D. 304, became very ſerious and alarming. During the whole winter he was confined to his palace; and his danger occaſioned a very general alarm. The rumour of his death was circulated, and very generally believed; and it was thought that the event was kept concealed till the arrival of Galerius, leſt the ſoldiers ſhould, in the mean time, according to cuſtom, proclaim a new emperor. At length, however, on the 1ſt of March, A.D. 305, he once more appeared in public, but ſo pale and emaciated, that he could ſcarcely have been recognized by thoſe to whom his perſon was the moſt familiar. Galerius, who had already threatened Maximian with a civil war, if he did not reſign the empire, arrived about this time at Nicomedia; with a view of obliging Dioclesian likewiſe to ſurrender the ſovereignty, ſince he was no longer able to diſcharge the functions of the imperial dignity. Whilſt the emperor demurred, offering, however, to ſhare the empire with him and Conſtantius, Galerius told him plainly, that if he did not reſign willingly, he would force him to abdicate. It was at length agreed, that Dioclesian and Maximian ſhould renounce the ſovereignty; that Conſtantius and Galerius ſhould, at the ſame time, be veſted with it; and that, in order to preſerve the form of government introduced by Dioclesian, two new Cæſars ſhould be appointed. Theſe meaſures, on the part of the ambitious Galerius, haſtened the execution of the purpoſe, which Dioclesian had previouſly formed, even during the ſplendour of a Roman triumph. Accordingly the ceremony of his abdication was performed on the 1ſt of May, A.D. 305, in a ſpacious plain, about three miles from Nicomedia. The emperor aſcended a lofty throne, and in a ſpeech, full of reaſon and dignity, declared his intention, both to the people and the ſoldiery, who were aſſembled on this extraordinary occaſion. As ſoon as he had diveſted himſelf of the purple, and delivered it to Maximin, whom at the ſame time he declared Cæſar, together with Severus, he withdrew from the gazing multitude; and traverſing the city in a covered chariot, he proceeded without delay to the favourite retirement which he had choſen in his native country of Dalmatia. On the ſame day Maximian, as it had been previouſly concerted between the two emperors, made his reſignation of the imperial dignity at Milan, tranſferring

ferring the purple to Severus, and declaring Conſtantius and Galerius emperors, as Diocleſian had done, he retired to Lucania. Lactantius aſcribes the reſignation of Maximian and Diocleſian to the intrigues and menaces of Galerius, and to the apprehenſion of a civil war, which his ambition led them to entertain. Conſtantine, however, who was then at Nicomedia, and lodged in the ſame palace with Diocleſian, aſſures us that the emperor, thinking himſelf no longer able to govern, on account of the fits to which he was ſubject, reſigned of his own accord; and the panegyriſts, who wrote at that time, mention his reſignation as a ſhining inſtance of greatneſs, generoſity, and an utter contempt of all human grandeur; and aſſert that both he and Maximian had agreed long before, and even bound themſelves by a ſolemn oath in the capital, to reſign the ſovereignty. Diocleſian paſſed the laſt nine years of his life at a country ſeat in the neighbourhood of Salona, on the ſpot where the city of Spalatro was afterwards built. About ſix or ſeven miles from the city of Salona he conſtructed a magnificent palace, ſome remains of which are ſtill viſible; for an account of which ſee SALONA.

In this retirement Diocleſian employed his leiſure hours in building, planting, and gardening. His anſwer to Maximian is deſervedly celebrated. When he was earneſtly ſolicited by that reſtleſs old man to reſume the reins of government and the imperial purple, he rejected the temptation with a ſmile of pity, calmly obſerving, that if he could ſhew Maximian the pot-herbs which he had planted with his own hands at Salona, he ſhould no longer be urged to relinquiſh the enjoyment of happineſs for the purſuit of power. In his converſation with his friends, he often acknowledged, that, of all arts, the moſt difficult was that of reigning; and he expreſſed himſelf on that topic with a degree of warmth which could only be the reſult of experience. "How often, as he was accuſtomed to ſay, is it the intereſt of four or five miniſters to combine together, to deceive their ſovereign? Secluded from mankind by his exalted dignity, the truth is concealed from his knowledge: he can ſee only with their eyes, he hears nothing but their miſrepreſentations. He confers the moſt important offices upon vice and weakneſs, and diſgraces the moſt virtuous and deſerving among his ſubjects. By ſuch infamous acts, added Diocleſian, the beſt and wiſeſt princes are ſold to the venal corruption of their courtiers." (Hiſt. Auguſt. p. 223, 224.) Although Diocleſian had retired from the diſtracting anxieties of government, he could not in his privacy remain ignorant of the troubles that afflicted the empire after his abdication, nor could he be indifferent to their conſequences. His tenderneſs, or at leaſt his pride, was deeply wounded by the misfortunes of his wife, Priſſe, and daughter Valeria, who, under the reign of Conſtantine, were both condemned and publicly executed, and their bodies were afterwards thrown into the ſea; and the laſt moments of Diocleſian were embittered by ſome affronts, which Licinius and Conſtantine might have ſpared the father of ſo many emperors, and the firſt author of their own fortune. Before his death, which happened at Salona, in the ninth year after his abdication, the 21ſt of his reign, the 68th of his age, and the 313th year of Chriſt, he was ſeized with an agitation of body and of mind, which allowed him no reſt either day or night, but he rolled himſelf ſometimes on the ground, and ſpent his whole time in ſighs, groans, and tears. According to ſome authors, he either ſtarved or poiſoned himſelf. His memory was much reſpected, and a magnificent tomb was erected to him, which was ſtill covered with purple in the time of Conſtantius, the ſon of Conſtantine. He was ranked among the gods; a prerogative, ſays Eutropius, which never was beſtowed upon any other man who died in a private ſtation. This apotheoſis cannot be laid to the charge of Conſtantine, who then profeſſed himſelf a Chriſtian; but it muſt be imputed to Licinius and Maximin, who had offended Diocleſian whilſt he lived, and who, without any charge to themſelves, might honour him after he was dead.

The abilities of Diocleſian, ſays Gibbon, were uſeful rather than ſplendid; he poſſeſſed a vigorous mind, improved by the experience and ſtudy of mankind; dexterity and application in buſineſs, a judicious mixture of liberality and economy, of mildneſs and rigour; profound diſſimulation under the diſguiſe of military frankneſs; ſteadineſs to purſue his ends; flexibility to vary his means; and, above all, the great art of ſubmitting his own paſſions, as well as thoſe of others, to the intereſt of his ambition, and of colouring his ambition with the moſt ſpecious pretences of juſtice and public utility. Like Auguſtus, Diocleſian may be conſidered as the founder of a new empire. Like the adopted ſon of Cæſar, he was diſtinguiſhed as a ſtateſman rather than as a warrior; nor did either of thoſe princes employ force, whenever their purpoſe could be effected by policy. Libanius writes (Orat. xiv.) that Diocleſian ſhewed himſelf in many, but not in all things, an excellent prince; and the emperor Julian (Orat. i.) commends him for having done many things that proved very uſeful to the public. He enacted many excellent laws, ſeveral of which are inſerted in the code, and he was ſo far from encouraging informers, that he commanded them to be executed when they could not ſupport their charge. He encouraged and preferred perſons of merit and virtue, diſcountenanced vice, encouraged the worſhip of the gods, and was, till ſeduced by Galerius, rather a friend than an enemy to the Chriſtians, of whom he had, till the year 303, great numbers both in his court and in his army. He was attentive to make plenty reign in his capital, in the armies, and in the whole empire. Nevertheleſs, with ſo many qualities worthy of eſteem, he knew little of the art of rendering himſelf amiable; and though he gloried in imitating Marcus Aurelius, he was far from copying his goodneſs. Beſides the cruel perſecution which he ordered againſt the Chriſtians, his government tended to the oppreſſion of the people. All hiſtory reproaches him with pride, oſtentation, and arrogance. Even his prudence degenerated into artifice and cunning, and inſpired ſentiments of ſuſpicion and diſtruſt. His economy bordered on avarice, and, if we may believe Lactantius, was ſometimes enforced with cruelty. It has been obſerved by Aurelius Victor, that no connection with him juſtified confidence, and that thoſe whom he called his friends could not depend upon a ſincere affection on his part. He was greatly addicted to building: and embelliſhed the ſeveral cities of the empire, particularly Rome, Carthage, Milan, and Nicomedia, with many ſtately edifices. Lactantius much blames him for his rage of building. At Nicomedia he indulged this paſſion to an extravagant and injurious degree. Here, ſays our author, he built a baſilic, there a circus, in another place a mint, and elſewhere an arſenal. For his wife he built a palace, and another for his daughter. In order to make room for thoſe new edifices, a great part of the city was taken from its inhabitants, who were obliged to migrate with their wives and children, as if their country had been ſeized by enemies. When theſe buildings were finiſhed, to the ruin of the provinces; they were again executed upon another plan. Then they were again pulled down and altered, perhaps to be again deſtroyed. Such was the madneſs which he manifeſted in his vain ambition of making Nicomedia equal to Rome. At Rome his baths were an immenſe building, the vaſt circumference of which, if it cannot, without hyperbole, be compared with an ancient writer, (Ammian l. xvi.) to the extent of a province, is, at leaſt,

leaſt, greater than that of many cities. In this building, beſides baths, were walks, places for exerciſe, and others for ſtudy; rows of trees, porticoes, great halls, and libraries. Crevier's Rom. Emp. vol. ix. x. Anc. Univ. Hiſt. vol. xiv. Gibbon's Hiſt. vol. ii.

DIOCLETIANOPOLIS, in *Ancient Geography*, an epiſcopal town of Thrace.—Alſo, an epiſcopal town of Phrygia.

DIOCLIA, in an epiſcopal town of Aſia, in the Pacatian Phrygia.

DIOCTAHÆDRIA, in *Natural Hiſtory*, the name of a genus of ſpars. The word is derived from the Greek δις, *twice*, οκτω, *eight*, and ἑδρα, *a ſide*. The bodies of this genus are ſpars compoſed of twice eight planes, or two octangular pyramids joined baſe to baſe, without any intermediate column. Hill's Hiſt. of Foſſ. p. 211.

DIODATI, John, in *Biography*, a celebrated preacher at Geneva, was born at Lucca about the year 1589, of a noble family of the Catholic perſuaſion, but having, at an early age, embraced the Proteſtant faith, he went to Geneva, where he ſtudied with ſo much ſucceſs, as, at the age of nineteen, to be deemed qualified for the profeſſorſhip of Hebrew in that univerſity. He was ſoon advanced to the theological chair, and acquired a high reputation as a preacher. In 1619, he was deputed with M. Tronchin to repreſent the Genevan clergy in the ſynod of Dort. Here he acted his part ſo well, that he was appointed one of ſix miniſters to draw up the Belgic confeſſion of faith, which was intended to preſerve the profeſſors of the reformed religion in Holland within the pale of Calviniſm. He died at Geneva in 1652, much regretted by the country and communion for which he renounced his family expectations, and the religion of his anceſtors. He was an elaborate writer, but his principal work was a tranſlation of the whole Bible into the Italian language. He publiſhed alſo a complete French tranſlation of the Bible, and a tranſlation of "Father Paul's Hiſtory of the Council of Trent;" and various other works. Moreri.

DIODIA, in *Botany*, (from Διοδος, a paſſing from one place to another, in alluſion, as Linnæus informs us, to its growing by way-ſides.) Linn. Gen. 51. Schreb. 67. Willd. Sp. Pl. v. 1. 580. Juſſ. 197. Gærtn. t. 25. Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Stellatæ*, Linn. *Rubiaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of two or three ſomewhat ovate, undivided, permanent leaves. *Cor.* of one petal, funnel-ſhaped; tube long and ſlender; limb ſmall, in four deep, ſpreading, lanceolate ſegments. *Stam.* Filaments four, briſtle-ſhaped, erect; anthers verſatile. *Piſt.* Germen inferior, roundiſh, with four angles; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma cloven. *Peric.* Capſule ovate, with four angles, crowned with the enlarged calyx, of two cells and two valves. *Seeds* ſolitary, ovate-oblong, poliſhed, convex, and furrowed on the outſide, flat on the inner.

Eſſ. Ch. Calyx two or three-leaved. Corolla of one petal, funnel-ſhaped. Capſules of two cells. Seeds ſolitary.

D. *virginiana*. Linn. Sp. Pl. 151. Jacq. Ic. Rar. v. 1. t. 29, is the only ſpecies which was known to Linnæus, or of which any figure exiſts. It was found by Clayton in Virginia, growing in watery places, and has not yet been cultivated in the gardens of Britain. Jacquin had it at Vienna, growing in the open air, but more vigorouſly in the ſtove, flowering from June to October, and ripening ſeed. It has no pretenſions to be reckoned an ornamental plant. The *root* is perennial. *Stems* ſeveral, red, decumbent and rooting, clothed with numerous, oppoſite, lanceolate, entire *leaves*, each about two inches long, and in a cultivated ſtate, rough only at the edge. *Stipulas* connate, fringed. *Flowers* axillary, ſolitary, ſeſſile, white, ſmall, the upper ſurface of their petals rough, and the calyx, according to Jacquin, moſtly conſiſting of two larger leaves, and a ſmaller one. In a wild ſpecimen, gathered by the celebrated John Bartram in Maryland, we find the leaves very rough all over with rigid points, and the fruit clothed with prominent briſtles, with three leaves to the calyx. *Diodia ſimplex*, *proſtrata*, *ſcandens* and *ſarmentoſa*, are four Weſt Indian ſpecies, ſmaller than the foregoing in their leaves and bloſſoms, of which the three laſt are ſomewhat woody. They were all gathered by Dr. Swartz, and are deſcribed in his *Flora Indiæ Occidentalis*, v. 1. D. *verticillata*. Vahl. Symb. v. 2. 28, gathered at Santa Crux by a Mr. Pflug, ſeems to differ from the original *Diodia* chiefly in having an upright ſtem. Theſe are all the ſpecies known. The habit of the genus is ſimilar to that of the far more numerous one *Spermacoce*.

DIODON. in *Ichthyology*, a genus of Branchioſtegous fiſhes, diſtinguiſhed by having the jaws bony, extended, and undivided; aperture of the gills linear; body covered on all ſides with long ſpines, which are ſtrong, and moveable, varied with white and black, hollow within, and covered with the common ſkin; no ventral fins. There are only five ſpecies of this remarkable genus at preſent known, unleſs ſome of the ſuppoſed varieties of the ſpecies Hyſtrix ought truly to be regarded as diſtinct ſpecies, as we are inclined to ſuſpect. They are inhabitants chiefly of the American ſeas.

Species.

Hystrix. Spherical; ſpines triangular. Gmel. *Le Guara*, Bloch. *Porcupine fiſh*.

The porcupine fiſh, or, as ſometimes called, the ſea porcupine, is a ſpecies of large ſize, growing to the length of two feet. The uſual ſhape is ſpherical, but it poſſeſſes the power of inflating or contracting itſelf at pleaſure, by means of an internal ſkin, or membrane, ſituated beneath the exterior, or ſpiny covering; the colour is a pale, or whitiſh grey, the back of a deeper caſt, and blueiſh, and the whole body is marked at the baſe of each ſpine by a round black ſpot, and the fins alſo are ſpotted. This fiſh, according to father Dutertre, affords an amuſing ſpectacle when taken with the hook and line baited with a piece of crab, or other ſimilar ſubſtance; after having played round the bait for ſome time, it makes various efforts to ſeize it, and at length faſtens upon it with a ſudden ſpring; but finding itſelf ſecured, it exhibits every mark of anger, inflating its body, and elevating its ſpines to the higheſt poſſible degree, and at intervals ruſhing with unavailing impetuoſity upon the pliable line, or beating about, as if endeavouring to wound in all directions. Till having at laſt tired itſelf by ineffectual ſtruggles, it ſuddenly expels the air from its body, and becomes entirely flaccid; but, on being drawn to the ſhore, it once more revives, redoubles its rage, and again inflates its body, and in this ſtate it is allowed to remain, with length of line ſufficient to admit it to expend its ſtrength in rolling about the ſhore, as it is impoſſible to touch it without danger till after its death. This ſpecies is a native of the Indian and American ſeas, and is conſidered as a coarſe and worthleſs fiſh, though ſometimes eaten by the inhabitants of the Weſt Indian iſlands. The ſkin of this fiſh is occaſionally taken off entire, and being dried in an inflated, or diſtended ſtate, ſerves the purpoſe of a lantern, being ſuſpended by the tail, and having the lighted candle placed in the inſide of the mouth. One of the ſuppoſed varieties of the ſea porcupine is of a ſomewhat rounded form, with ſhort triangular ſpines; another is roundiſh, with the ſpines triangular at the baſe; and a third conic oblong, with the ſpines long, and a little rounded.

Atinga. Oblong; ſpines on the body round. Bloch. &c.

A ſpecies much reſembling the former, but of a more lengthened form; its general colour is grey, deeper on the back, and tinged with a caſt of pink beneath. The whole body is marked, as well as the fins, with numerous round black ſpots, as in the former ſpecies. In its manners of life, it reſembles the porcupine fiſh, but grows to ſcarcely more than half its length. The ſpecies is conſidered as poiſonous, unleſs cleaned with the greateſt care, and, according to Piſo, if the leaſt quantity of the gall ſhould happen to fall on, and mix with the fleſh, it produces the moſt violent ſymptoms; the tongue becomes immoveable, the limbs ſtiffen, and a cold ſweat enſues, followed by certain death, unleſs the poiſon be expelled by immediate medical aid. This fiſh is a native of the American ſeas round the Cape of Good Hope.

Orbicularis. Body round and covered with ſhort ſpines. Bloch. *L'orbe Hériſſon. Diodon Atinga var β*, Linn.

This ſpecies inhabits the ſea of Jamaica, the Cape of Good Hope, and the Molucca iſles; grows to the length of nine or ten inches, and feeds on ſhells and cruſtaceous animals. In point of ſhape this ſpecies is almoſt ſpherical; the ſpines ſtrong, and ſhort, with the baſes broad, and ſomewhat reticulating the ſkin; the colour is rufous above, beneath paler. This, like the former, is eſteemed poiſonous.

Plumieri. Elongated, blueiſh, with white ſpots, and contracted neck. *Diodon Plumieri*, Cepede.

Reſembles the oblong diodon, but is longer in proportion, and has a conſiderable contraction behind the head; the general colour is blueiſh, with numerous ſmall round white ſpots. This ſpecies is a native of the American ſeas in warm latitudes, where it was diſcovered by father Plumier.

Liturosus. Browniſh, beneath whitiſh, and marked on the upper part with black patches. Shaw. *Dindon tacheté*, Cepede.

This is a native of the Indian ſeas, and is deſcribed by Commerſon. Its ſhape is rather globular, the colour brown above, beneath whitiſh, with a large lunate black ſpot on the nape, the horns of which point towards the eyes. On each ſide the body a ſomewhat oval patch, ſituated above the pectoral fin, and two others placed tranſverſely, the firſt beneath the eye, the ſecond between the eye and pectoral fin: throat marked by a duſky cloud, and on the back a round ſpot encircling the dorſal fin; ſpines white with brown tips, and conſiderably longer on the back than towards the abdomen. All the fins are greeniſh.

The diodon mola of Gmelin is referred to the tetrodon genus. See Tetrodon *Mola*.

DIODORI Insula, in *Ancient Geography*, an iſland of Ethiopia, in the Arabic gulf, near Egypt, according to Pliny and Ptolemy.

DIODORIDA, a town of Aſia, in Meſopotamia.

DIODORUS, in *Biography*, a diſciple of the Megaric ſchool, was a native of Caria, and a great adept in that kind of verbal combat which prevailed among perſons of his ſect. It is ſaid that a queſtion was propoſed to him in the preſence of Ptolemy Soter, by Stilpo, one of his fraternity, which he required *time* to anſwer; and on this account he was ridiculed by Ptolemy, and denominated *Chronus*. Mortified at this defeat, he wrote a book on the queſtion, and, nevertheleſs, died of vexation. He is the reputed author of the famous argument or ſophiſm againſt motion: if any body be moved, it is moved either in the place where it is, or in a place where it is not, for nothing can act or ſuffer where it is not; and, therefore, there is no ſuch thing as motion. Diodorus was ſuitably recompenſed for the invention of this ſophiſm. Having diſlocated his ſhoulder, the ſurgeon, who was ſent for, kept him for ſome time in torture, whilſt he proved, from his own mode of reaſoning, that the bone could not have *moved* out of its place. He has been improperly reckoned among the atomic philoſophers. Brucker's Hiſt. Phil. by Enf. vol. i.

Diodorus, a Peripatetic philoſopher, with whom the uninterrupted ſucceſſion of the Peripatetic ſchool terminated.

Diodorus, named *Siculus*, an ancient hiſtorian, who flouriſhed in the times of Julius and Auguſtus Cæſar, was a native of Agyrium in Sicily. He devoted himſelf to the compoſition of hiſtory, and ſpent thirty years in his ſtudies and enquiries, travelling to the very places in Europe and Aſia, which had been the theatre of important tranſactions, and inveſtigating the facts with the greateſt care and attention. A ſmall part of his labours has come down to our times. His great work was entitled Βιβλιοθηκη ἱστορικη, or "The Hiſtoric Library," in forty books on Univerſal Hiſtory, of which only fifteen and ſome fragments remain. This hiſtory was divided into the periods before the Trojan war, and from that to the death of Alexander, and thence to the commencement of Cæſar's wars in Gaul. His ſtyle is commended by Photius, as being that kind of middle diction which is ſuitable to hiſtory; but others have not thought ſo favourably of it. He has been charged with chronological errors, fable, and trivial narrative; but the fabulous hiſtory of the early ages has been alleged as an apology. Upon the whole, his hiſtory is valuable, and we have to regret the loſs of his laſt books. The beſt editions of this work are thoſe by Stephanus, Par. 1559; of Rhodomannus, Hanau, 1604; and of Weſſelingius, in two vols. fol. Amſterd. 1746.

Diodorus, deſcended from a good family, was probably born at Antioch, in which city he long reſided, and was ordained biſhop of Tarſus, in Cilicia, about the year 378. He died in 394, or ſooner. Whilſt he was preſbyter, he had the direction of a ſchool in or near Antioch, where he inſtructed young perſons in the knowledge of the Scriptures, and the principles of religion. The moſt eminent of his diſciples were Maximus, biſhop of Sileucia, in Iſauria, Theodore, biſhop of Mopſueſtia, in Cilicia, and John Chryſoſtom, biſhop of Conſtantinople, the latter of whom calls him, in one of his orations, his father. He was a firm adherent to the orthodox cauſe under the perſecutions of the Arians, and conducted himſelf with ſo much prudence, that he ſeems to have enjoyed a peaceable epiſcopate till his death. In the firſt council of Conſtantinople he was held in ſuch reſpect, as to be appointed one of the biſhops, to whoſe ſuperintendance the eaſtern churches were entruſted. His works were numerous, and conſiſted of apologies for the Chriſtian religion, controverſial treatiſes againſt the Manichers, &c. and principally commentaries on almoſt all the books of the Old Teſtament, and ſome of the New, which were deſtroyed, as ſome ſay, by the Arians, and, according to others, by the Athanaſians. Some fragments ſtill remain, which are found in the Catena Patrum Græcorum. The loſs of his writings is the more to be deplored, as they diſplayed great learning, the mode of interpreting Scripture by adhering to the literal ſenſe, and an acquaintance with Origen's Hexapla. Diodorus is much commended by Theodoret, Baſil, and other fathers of the church. Suidas has given a catalogue of his works, extracted from the fragments of Theodore. Cave's H. L. vol. i. ad Sæc. Arian. Lardner's Cred. vol. iii.

DIODURUM, in *Ancient Geography*, a place of Gaul, ſituated, according to the Itinerary of Antonine, between Durocaſſes (Dreux) and Lutetia, and ſuppoſed by D'Anville to be Jouare, near Pontchartrain.

DIOECESIS, Διοικησις, among the Romans, a prefecture of

of ſeveral provinces joined together, under the ſame governor, called præfectus. See PREFECT and DIOCESE.

DIOECIA, in *Botany*, (from δις, *double*, and οικια, *a houſe*,) the 22d claſs of the ſexual, or artificial ſyſtem of Linnæus, containing ſuch plants as have barren, or male, flowers on one individual, and fertile, or female, ones on another of the ſame ſpecies. Such flowers are termed dioecious; (ſee DIOICI, FLORES.) This claſs is ſtrictly natural and invariable only when the two kinds of flowers differ in other parts of their ſtructure, beſides their eſſential difference in the organs of impregnation, as in the Hop, *Humulus Lupulus*, becauſe ſuch flowers can never vary ſo as to become united. A ſimilar difference of ſtructure, however, in the acceſſory parts of the bloſſoms, is much more prevalent in the claſs *Monoecia*, whoſe barren and fertile flowers grow on the ſame plant, like the Oak, the Haſel, the Walnut, &c., than in the *Dioecia*. See Sm. Introd. to Botany, 470.

The Orders of this claſs are reckoned but eight in the work laſt cited, though Linnæus makes them much more numerous. They are diſtinguiſhed by the number or connection of the ſtamens, and are called, 1. *Monandria*, 2. *Diandria*, (of which *Salix*, the Willow, is an example,) 3. *Triandria*, 4. *Tetrandria*, 5. *Pentandria*, (containing the Hop, Hemp, Piſtacia-nut, and ſome others,) 6. *Hexandria*, 7. *Polyandria*, (compriſing all dioecious plants with eight or more ſtamens,) and 8. *Monadelphia*, in which the filaments are united; of this laſt the Fir, Yew, and Juniper, are inſtances. S.

DIOGENES, in *Biography*, a famous philoſopher of the Cynic ſect, was born in the 3d year of the 91ſt Olympiad, B. C. 414, at Sinope, a city of Pontus. His father was a banker, who, being convicted of debaſing the public coin, was obliged to leave his country. This circumſtance occaſioned the removal of his ſon to Athens, where he offered himſelf as a pupil to Antiſthenes, who, being in a peeviſh humour, refuſed to admit him. As he ſtill perſiſted in his application, the ſurly philoſopher lifted up his ſtaff to repulſe him, upon which young Diogenes ſaid; "Beat me if you pleaſe; I will be your ſcholar." Antiſthenes, at length, received him; and he became his intimate companion and friend. Having thus choſen his maſter, he adopted his principles, and reſembled him in character: determining to diſtinguiſh himſelf by a contempt of riches and honours, and by his indignation againſt luxury. He wore a coarſe cloak; carried a wallet and a ſtaff; made the porticoe, and other public places, his habitation; and depended upon caſual contributions for his daily bread. Diſappointed in obtaining a cell as ſoon as he expected, he is ſaid to have taken up his abode in a tub, or large open veſſel, in the "Metroum." This tub, which was probably not a ſettled reſidence, but a temporary expreſſion of indignation and contempt, is celebrated by Juvenal, (Sat. xiv. v. 308.)

"—— Dolia nudi, &c."
"Safe in his tub, the naked Cynic lives
Fearleſs of fire: break up his houſe; next day
Brings him a new one, or repairs the old."

This tub is ridiculed by Lucian (De Scrib. Hiſt.) and mentioned by Seneca (Ep. 90.); but no notice is taken of this circumſtance by other ancient writers who have mentioned this philoſopher; not even by Epictetus, who (Ap. Arr. l. iii. Diſſ. 24.) relates ſeveral particulars of his life. Whether this piece of hiſtory be true or not, there is no doubt of his having practiſed the moſt hardy ſelf-controul, and the moſt rigid abſtinence, and of his having depended upon charity for his ſcanty ſupport. In conformity to the principles which he had adopted, and the character he ſuſtained, he reprehended the Athenians, and eſpecially thoſe of the higher ranks, with great freedom and ſternneſs. His reproofs, however, though very pungent, manifeſted ſo much ingenuity, as to excite even the admiration of thoſe againſt whom they were directed. He uniformly inculcated patience of labour and pain, frugality, temperance, and an entire contempt of pleaſure. But though his rigid diſcipline procured for him from ſome reſpect and admiration, it ſubjected him to contempt and indignity from others. But to one and the other he appeared equally indifferent, and preſerved on all occaſions a perfect ſelf-command.

Diogenes, in his old age, is ſaid to have ſailed to the iſland of Ægina; and having met with pirates, he was carried into Crete, and expoſed to public ſale. Being aſked what he could do? he replied, "I can govern men, and therefore ſell me to one who wants a maſter:" Xeniades, a wealthy Corinthian, being ſtruck by this ſingular reply, purchaſed him; upon which Diogenes told him, "I ſhall be more uſeful to you as your phyſician, than as your ſlave." Upon their arrival at Corinth, Xeniades gave him his liberty, and committed to his direction the education of his children, and the management of his domeſtic concerns. Xeniades had ſo much reaſon to be ſatisfied with his judgment and fidelity, that he uſed to ſay, the gods had ſent a good genius to his houſe. He accuſtomed his pupils to the diſcipline of the Cynic ſect, and took greater pains to inure them to habits of ſelf-command, than to inſtruct them in the elements of ſcience. However, he was not negligent in teaching them leſſons of moral wiſdom, which he inculcated by ſententious maxims: and he allowed them the moderate uſe of athletic exerciſes and hunting. The young men, pleaſed with their preceptor, treated him with reſpect, and recommended him to their parents. During his reſidence at Corinth, he frequently attended the aſſemblies of the people at the Craneum, a place in its vicinity, and at the Iſthmian games. Here he appeared under the character of a cenſor, ſeverely laſhing the follies of the times, and inculcating rigid leſſons of ſobriety and virtue. At one of theſe aſſemblies the conference between Alexander the Great and Diogenes is ſaid to have happened. Plutarch relates the ſtory thus: Alexander received the congratulations of all ranks on his being appointed, after the death of his father, to the command of the Grecian army in their projected expedition againſt the Perſians. Diogenes was abſent on this occaſion, and Alexander expreſſed his ſurpriſe at this circumſtance. Wiſhing to gratify his curioſity by the ſight of ſuch a philoſopher as Diogenes, he viſited the Craneum, where he found the philoſopher ſitting in his tub in the ſun. The king came up to him in the crowd, and ſaid, "I am Alexander the Great;" to which Diogenes replied, in a ſurly tone, "and I am Diogenes the Cynic." Alexander, requeſting to know if he could render him any ſervice, received for anſwer, "Yes," ſays he, "do not ſtand between me and the ſun." Alexander, ſurpriſed at the magnanimity of this reply, ſaid to his friends, "If I were not Alexander, I would be Diogenes." There are ſeveral circumſtances in this narrative, which ſuggeſt ſome doubts as to its truth; but it is not improbable that Diogenes, who, at the beginning of the 111th Olympiad, when Alexander held the general aſſembly of the Greeks, was upwards of 70 years old, might often appear in the public walks of Corinth, and that Alexander, indulging a curioſity to ſee a man of his ſingular character, might put himſelf in his way: nor is it unlikely, that the ſurly Cynic might manifeſt his contempt for kings, by treating him with ſome kind of rudeneſs, ſimilar to what has been above related.

As far as we can depend on the repreſentations of the ancients,

cients, Diogenes was a philoſopher of a penetrating genius, not unacquainted with learning, and deeply verſed in the knowledge of mankind. He alſo poſſeſſed an elevated mind, ſuperior to the viciſſitudes of fortune, patient of ſuffering, and incapable of fear. Contented with a little, he deſpiſed the luxuries of the age. Earneſtly deſirous of correcting and improving the public manners, he cenſured réigning follies and vices with a ſteady confidence, ſometimes degenerating into ſeverity. His freedom gave great offence to multitudes; and, of courſe, he ſuffered much obloquy, and was made the ſubject of ludicrous and diſgraceful calumny. But we can hardly believe that a perſon, who has been extolled by ſome of the moſt eminent philoſophers for his ſobriety and virtue, and repreſented as one endowed with divine wiſdom, ſhould have been capable of committing the groſſeſt indecencies, ſome of which have been charged upon him. The ſtory of his intercourſe with Lais, the celebrated courtezan, is inconſiſtent with chronology; and as it chiefly depends on the teſtimony of Athenæus, we ought to recollect, that this writer has amaſſed a variety of tales to the diſcredit of philoſophy. From the charge of philoſophical pride, however, the moſt partial advocates of Diogenes cannot acquit him: hence, he was led to treat other philoſophers, and even magiſtrates and princes, with contempt; and he reproved vice, wherever he found it, with bitterneſs, and even with ſcurrility. True wiſdom cannot juſtify this conduct, nor did it require his taking the cloak and wallet of a mendicant. The time and manner of his death are not ſatisfactorily aſcertained. It is moſt probable that he died at Corinth of mere decay, in the 90th year of his age, in the 1ſt year of the 114th olympiad, B. C. 324. He was buried honourably by the Athenians at the public expence; a column of Parian marble, terminated by the figure of a dog, was placed over his tomb; and his friends erected many brazen ſtatues to his memory.

The philoſophy of Diogenes, which was practical, conſiſts of the following heads:—"Virtue of mind, as well as ſtrength of body, is to be acquired chiefly by exerciſe and habit. Nothing can be accompliſhed without labour, and every thing with it. Even the contempt of pleaſure may, by habit, become pleaſant. All things belong to wiſe men, to whom the gods are friends. The ranks of ſociety originate from the vices and follies of mankind, and are, therefore, to be deſpiſed. Laws are neceſſary in civilized ſtates; but the happieſt condition of human life is that which approaches the neareſt to a ſtate of nature, in which all are equal, and virtue is the only ground of diſtinction. The end of philoſophy is to ſubdue the paſſions, and prepare men for every condition of life."

The following maxims or apothegms of Diogenes, ſelected from a variety of others, may be gratifying to the reader:—"I trample under foot the pride of Plato," ſaid Diogenes, treading upon his robe. "Yes," ſaid Plato, "with greater pride of your own." To a friend, who adviſed him to indulge himſelf in his old age, he ſaid, "Would you have me quit the race when I have almoſt reached the goal." Plato, having defined man a two-legged animal without wings, Diogenes plucked off the feathers from a cock, and turning him into the academy, exclaimed, "See Plato's man." In reply to one who aſked him at what time he ought to dine, he ſaid, "If you are a rich man, when you will; if you are poor, when you can." "How happy," ſaid one, "is Calliſthenes in living with Alexander." "No," ſaid Diogenes, "he is not happy; for he muſt dine and ſup when Alexander pleaſes." Plato, diſcourſing concerning ideas, ſpoke of the abſtract idea of a table and a cup. Diogenes ſaid, "I ſee the table and the cup, but not the idea of the table and the cup." Plato replied, "No wonder, for you have eyes but no intellect." His anſwer to an invitation from Craterus to come and dine with him was, "I had rather lick ſalt at Athens, than ſit down to the richeſt feaſt with Craterus." Being aſked what countryman he was, he replied, "A citizen of the world." To one that reviled him he ſaid, "No one will believe you when you ſpeak ill of me, any more than they would believe me if I were to ſpeak well of you." Hearing one of his friends lamenting that he ſhould not die in his own country, he ſaid, "Be not uneaſy, from every place there is a paſſage to the regions below." "Would you be revenged upon your enemy," ſaid Diogenes, "be virtuous, that he may have nothing to ſay againſt you." Laertius, l. vi. § 20, &c. Arrian Epict. l. iii. Diſſ. 21. Brucker's Hiſt. Phil. by Enf. vol. i.

Diogenes (not the Cynic), the ancient Greek writer on muſic, attacked by the αμουσος, Philodemus, whoſe abuſe of muſic has been recovered from the cinders of Herculaneum.

Diogenes, ſurnamed the Babylonian, from his birth-place, Seleucia, near Babylon, flouriſhed in the ſecond century, B C. He was the diſciple of Chryſippus, and the ſucceſſor of Zeno of Tarſus, where he taught the principles of his ſect with unwearied diligence, and a high reputation. He was the author of ſeveral works on divination, the laws, learning, &c. which have been referred to with reſpect by Cicero and others. He is ſaid to have lived to the age of 88 years, and philoſophized to the laſt. That he was highly eſteemed by his contemporaries is evident from his being appointed in conjunction with Carneades, the head of the academics, and Critolaus, the chief of the peripatetic ſchool, to the embaſſy to Rome. As a proof how well his practice conformed to his principles, we are told, that when he was once diſcourſing againſt anger, an inſolent young man, with the hope of expoſing him to the ridicule of his audience, ſpat upon him, and otherwiſe contumeliouſly treated him, upon which the philoſopher obſerved with meekneſs, "I am not angry, but I am doubtful whether I ought to be ſo." Bayle. Brucker by Enfield.

Diogenes Laertius, ſo named from the ſuppoſed place of his birth, Laerta, or Laertes, in Cilicia, was a Greek biographical writer; who is ſuppoſed to have flouriſhed according to Voſſius about the time of the Antonines, or ſomewhat later. Others, however, have thought it more probable that he lived under Severus and his ſucceſſors, and that his book of the "Lives," &c. was written about the year 210, in which opinion Dr. Lardner acquieſces. As an author the principal work of Diogenes is entitled "The Lives, Opinions, and Apothegms, of celebrated Philoſophers," in ten books, which has been regarded by ſome as a very valuable repoſitory of materials, for the hiſtory of philoſophy; but the character given of it by Brucker is, that the author "has collected from the ancients with little judgment, patched together contradictory accounts, relied upon doubtful authorities, admitted as facts, many tales which were produced in the ſchools of the ſophiſts, and has been inattentive to methodical arrangement." The work appears, upon the whole, to have been the production of a credulous and feeble mind. He alſo compoſed a book of epigrams, to which he refers. Little of his hiſtory is known, but he is ſuppoſed to have been inclined to the Epicurean philoſophy. His Life of Epimenides contains a paſſage which ſerves to illuſtrate the inſcription on the altar at Athens, To the unknown God, mentioned Acts, xxvii. 16—23. See Altar. The beſt edition of his "Lives, &c. is that of Meibomius, Amſt. 1692, 2 vols. 4to. with the obſervations of Menage. Brucker's Hiſt. Philos. by Enfield.

DIOGENES APOLLONIATES, a native of Crete, and a philoſopher of the Ionic ſect, flouriſhed about the 17th Olympiad, or 500 years B. C. Having ſtudied under Anaximenes, he ſucceeded Anaxagoras at Athens, where he taught philoſophy and eloquence for ſome time with great reputation. Either his doctrines were unpopular, or his ſucceſs created jealouſy, and he was obliged to leave the city at the peril of his life; and from this period nothing more is recorded of him. Little is known of the peculiarity of his ſentiments, but he appears to have held, that the air poſſeſſed a divine intelligence, and is the firſt principle in nature: that the number of worlds is infinite, and that they were formed by an exertion of the powers of rarefaction and condenſation; and that the centre of the earth, which is globular, is in the centre of the whole. Moreri. Brucker by Enfield.

DIOGENIS PROMONTORIUM, in *Ancient Geography*, a montory of Ethiopia, upon the Arabic gulf. Ptol.

DIOGNETUS, in *Biography*, a philoſopher, who flouriſhed in the reign of the emperor Marcus Aurelius, and who was one of the preceptors of that prince, by whom he was inſtructed in philoſophy, and other branches of important knowledge. He is mentioned with great reſpect by Juſtin, in whoſe works, publiſhed by Henry Stephens in 1592, an epiſtle to Diognetus is inſerted. By Lardner, and other judicious critics, the claim of this epiſtle to authenticity has been doubted. Diognetus was highly reſpected by his contemporaries, as well as greatly beloved by his pupil, Marcus Aurelius. Lardner.

DIOICI, FLORES, dioecious flowers, in *Botany*, have ſtamens in one individual, and piſtils in another, on ſeparate plants of the ſame ſpecies. Sometimes this is accompanied with no difference in the other parts of ſuch flowers, as the calyx or corolla, and therefore the organs of impregnation are liable to meet in the ſame flower in other plants of the ſame natural genus, as happens in *Lychnis*, *Valeriana*, *Urtica*, *Rumex*, &c. They ſtill more frequently meet in flowers of the ſame ſpecies, that are partly monoecious or dioecious, witneſs many exotic trees, and numerous graſſes, referred by Linnæus on that account to his 23d claſs, *Polygamia*, as well as our Engliſh Maple, Sycamore and Aſh. Hence, ſuch plants have been removed in the *Flora Britannica* to the united claſſes, and no genera left in *Polygamia* that have not a difference of ſtructure in the acceſſory parts of their flowers. This has been approved by all ſcientific botaniſts who have ſubſequently conſidered the matter. When flowers are perfectly monoecious or dioecious, and ſuch diſtinctions are accompanied by a difference in their acceſſory parts, as in *Zannichellia*, *Carex*, *Valiſneria*, and ſome others, eſpecially when there is moreover a difference of inflorescence, as in *Quercus*, *Corylus*, *Humulus*, &c. nothing can be more natural, conſtant, or convenient, than ſuch a character. It is far otherwiſe when the male and female flowers are ſo much alike, that there are rudiments of each part in the contrary flower. Thus, *Rhodiola* is merely a *Sedum*, with ineffectual ſtamens on one plant, and abortive piſtols on another. See DICLINIA. S.

DIOKO-WAR, or DIACOVAR, in *Geography*, a town of Sclavonia; 16 miles S. W. of Eſzek.

DIOMEDÆ, INSULÆ, in *Ancient Geography*, iſlands of the Adriatic ſea, according to Strabo, Ptolemy, and Pliny. They are now the iſlands of "Tremiti." One of theſe iſlands was called *Teutria*, and the other *Diomedea* and *Trimetus*. They had to the ſouth that part of Italy in which was ſituated mount Garganus.

DIOMEDEA, in *Ornithology*, a genus of the aquatic or marine kind, the albatroſs of Engliſh navigators. Theſe birds have the bill ſtraight, with the upper mandible hooked at the point, and the lower truncated; the noſtrils oval, wide, prominent, and lateral; tongue very ſmall; and feet three-toed, all placed forward.

Species.

EXULANS. White, back and wings lineated with white; bill pale yellow, legs fleſh colour; quill-feathers black; tail rounded and lead colour. Gmel.—*Diomedea exulans*, Linn.—*Plautus albatrus*, Klein.—*Tchaiki*, Pallas.—*Man of war bird*, Grew.—*Wandering albatroſs*, Arct. Zool.

This ſort of albatroſs is larger than the ſwan, meaſuring from three to four feet in length; and its general expanſion between the wings, when opened and ſtretched out, about ten feet. Many voyagers ſpeak of them as far exceeding even theſe dimenſions. One expanding to the breadth of eleven feet ſeven inches, is mentioned in Parkinſon's voyage, another of twelve feet in the Bankſian MS. One in the Leverian collection is ſaid to have meaſured thirteen feet; and if we may credit Ives, an albatroſs of this kind was ſhot off the Cape of Good Hope, which expanded ſeventeen feet and a half. The bill of this bird is of a dirty yellow; the crown of the head pale cinereous brown, and the legs fleſh colour. The young birds are ſaid to be brown, becoming gradually whiter as they advance towards maturity.

Albatroſſes are very abundant in many parts without the tropics, both to the north and ſouthward, and are in particular found in every temperate ſouthern latitude as far as the polar regions have been yet explored. Forſter tells us, they are never ſeen in the torrid zone. They are ſeen in vaſt flocks in Kamtſchatka, and the adjacent iſlands, about the end of June, and their arrival is a ſure preſage of the ſhoals of fiſh approaching. They are voracious birds, and often ſwallow a fiſh of four or five pounds weight; but as they cannot take the whole of it into their ſtomach at once, they are often caught with the tail hanging out of their mouth, and in this ſituation are knocked down themſelves by the natives. When caught, they defend themſelves ſtoutly with the bill; their cry is harſh and diſagreeable, and reſembles the braying of the aſs, or rather, according to Clayton, that of a trumpet, ſuch as the children buy at fairs. They are known to breed in Patagonia and the Falkland iſlands, and part of New Zealand bears the name of Albatroſs Point from this circumſtance. The neſt is made on the ground with earth, its ſhape is round, ſtands about a foot in height, and is indented at the top. The egg is larger than that of a gooſe, of a white colour, with a few dull ſpots at the broadeſt end; theſe eggs are eſteemed good for eating, but poſſeſs this remarkable peculiarity, that the white never becomes hard by boiling.

While the female is ſitting, the male is conſtantly on the wing, and ſupplies her with food; and during this time they are ſo tame, as to ſuffer themſelves to be puſhed off the neſt while their eggs are taken out. But their chief deſtruction ariſes from the perſecution of the New Zealand falcon, which the moment the female gets off the neſt, darts upon it, and flies away with the eggs. The albatroſs itſelf has its enemies likewiſe, particularly a ſort of gull of a dark colour, like the ſkua. This wily antagoniſt, aware of his inferiority of ſtrength, endeavours to attack the albatroſs underneath, and to prevent which, the latter is obliged to ſettle on the water. Theſe birds are often taken by the natives of Kamtſchatka, by means of a hook baited with a fiſh: they are caught chiefly for the ſake of their inteſtines, a particular part of which is blown up as a bladder, and ſerves as floats to buoy up their nets in fiſhing. Of the bones they make tobacco pipes, needle caſes, and other uſeful things; the fleſh is not in much requeſt, being hard and unſavoury. Hawkeſworth,

however, mentions that they were eaten by our voyagers: as ſoon as caught, they were ſkinned, and ſoaked in ſalt water till next morning; then parboiled, and the liquor being thrown away, ſtewed with freſh water till tender, and being ſerved up with ſavoury ſauce, they were much commended. The albatroſs feeds chiefly on marine animals.

Two varieties of the ſpecies *exulans* are deſcribed in the Gmelinian Syſtema, one of which is brown, with the upper part blackiſh; the bill red, with the tip blackiſh, down cinereous, and whitiſh towards the head. The other is white; the region of the ſhoulders, wings, and tail, blackiſh brown; head, and upper part of the neck, deep ſtraw colour; and the upper mandible white or reddiſh, the lower red, with a white keel.

Spadicea. Deep cheſnut, front, orbits, chin, throat, lower quill-feathers, abdomen and legs white; bill ochraceous white. *Diomedea ſpadicea*, Gmel. *Chocolate albatroſs*, Cook's Voyage.

This is ſmaller than the foregoing, meaſuring little more than three feet in length. The plumage is, in general, of a fine deep chocolate, paleſt beneath; the tail is ſhort and rounded, and the legs blueiſh white, with white claws. This varies in having more or leſs white about the head, and inhabits the South ſeas. A kind of albatroſs, entirely of a grey brown colour, with the bill and legs pale, is found in China, and has been conſidered as a variety of this ſpecies: its length is two inches and a half.

Chlororhynchos. White; bill black; keel of the upper mandible and baſe of the lower yellow; body above black blue, beneath white. Gmel. *Yellow noſed albatroſs*. Lath.

Length about three feet and breadth ſeven, the bill black, with the upper ridge and tip yellow, and the baſe of the under mandible is alſo yellow. The head is grey, and between the bill and eyes is an obſcure black ſpot, and another over the eye. The hind part of the neck is duſky, the lower part white; back, ſcapulars, and wings duſky blue black; rump and under part of the body white; the tail duſky; the legs pale yellowiſh white, with the fore part and webs duſky. This ſpecies is met with in the ſouthern hemiſphere from 30 to 60 degrees round the pole. This bird is obſerved to fly about five or ſix feet above the ſurface of the water.

Fuliginosa. Brown; head, bill, tail, quill-feathers and claws, ſooty brown; area of the eyes white. Gmel. *Sooty or brown albatroſs*, Forſter. *Albatroſs with a white eyebrow*, Cook's Voyage.

Inhabits the ſeas within the Antartic circle, is about the ſize of a gooſe, and meaſures about three feet in length. The bill is black; the irides pale yellow; at each angle of the eye a nictitating membrane. The general colour of the plumage is brown; the head and tail inclining to black or ſoot colour; for a ſmall ſpace above, behind and beneath the eye, the feathers are white, but not on the fore part of it; the quills and tail are dark brown, nearly black; the ſhafts of both white, and the latter pointed; legs pale browniſh lead colour; claws black.

Obſerved throughout the ſouthern ocean within the Antartic circle.

DIOMEDES, in *Biography*, was ſon of Tydeus, king of Etolia, and afterwards king of Argos himſelf. He led his ſubjects to Troy in numbers ſufficient to man eighty ſhips; hence he became one of the principal commanders at the Trojan war, and Homer has made him one of the moſt diſtinguiſhed heroes of his Iliad. After the deſtruction of Troy he returned to Argos, where he is ſaid to have found his wife connected with an adulterer, and plotting with him againſt the life of her huſband. He therefore embarked again, and after much travelling, ſettled with the companions of his fortunes at Daunia, on the Adriatic coaſt of Italy, where he married the daughter of the king, and founded the city of Argyrippa, afterwards called Arpi. Gen. Biog.

Diomedes, in *Geography*, the name of an iſland near the promontory of Siberia, on the N. E. point of the continent.

DIOMEDIA, in *Ancient Geography*, a town of Italy, in the Daunian diſtrict, mentioned by Virgil.

DIOMEDIS Insula, an iſland of Italy, at the bottom of the gulf which lies to the eaſt of Aquileia. It is now called *Belforte*.

Diomedis *Stabulum*, a town of Thrace, which belonged to king Diomedes, called by Mela "Diomedis Turris."

Diomedis *Avis*, in *Ornithology*, the name of a bird of the web-footed kind, with a ſlender beak, hooked at the end, and with its hinder toe not connected by the membrane that joins the reſt. It is of the ſize of a common hen, but its neck and legs are much longer; its colour is a duſky, and ſomewhat greyiſh brown, and under the belly there is more or leſs white; its beak is of a fine red, or in ſome of a yellowiſh colour, with a black end. It is found in the Inſula Diomedea, now called Tremiti, in the Adriatic ſea, and is ſaid to be peculiar to that place. See Shear-*Water*.

DION, in *Biography*, an illuſtrious inhabitant of Syracuſe, who, deriving an ample inheritance from his father, Hipparinus, became a diſciple of Plato, invited by Dionyſius the Elder to his court at Syracuſe. The philoſopher was highly pleaſed with his ſcholar, and ſpeaks in high terms of his attention and proficiency. Being a philoſopher in practice, as well as ſpeculation, Dion eſcaped the diſſoluteneſs of the licentious capital, attached himſelf to the cauſe of liberty, and took part with his preceptor in the perſecutions which he underwent from the tyrant. He was nearly connected with Dionyſius by having married his daughter, and by his ſiſter's being one of his wives; and he was alſo much eſteemed by him, ſo as to be employed in ſeveral important embaſſies. At the acceſſion of Dionyſius the Younger, B. C. 366, he maintained conſiderable influence by virtue of his character and his wealth. At his requeſt, Plato was again invited to the Syracuſan court; and, in order to counteract his authority, the courtiers obtained the recal of Philiſtus, a man notorious for his adherence to arbitrary principles. This faction determined to ſupplant the credit of Dion and his favourite philoſopher; and availed themſelves of a real or ſuppoſititious letter, to fix upon him the charge of treaſon. Dion, precluded from ſelf-defence, was tranſported to Italy; and from thence proceeded to Greece, where he was received with great honour. At Athens he attended the academy, and the Lacedæmonians conferred upon him the freedom of their ſtate. At length Dionyſius became jealous of his popularity, ſtopped his remittance, confiſcated his eſtates, and compelled his wife, who had been left at Syracuſe as an hoſtage, to marry another perſon. Dion, juſtly incenſed at this uſage, determined to expel Dionyſius. Plato reſiſted his intention; but, encouraged by other friends, he aſſembled a body of troops, and, with a ſmall force, ſailed for Sicily, and landed at Minoa, a town belonging to the Carthaginians. Availing himſelf of the abſence of Dionyſius upon an expedition to Italy, he advanced to the capital, and was received at the gates of the city, amidſt the acclamations of the people. At length Dionyſius arrived; but, after ſeveral conflicts and ineffectual propoſals of accommodation, he was obliged to make his eſcape to Italy. Dion, poſſeſſing to a great degree the auſterity and reſerve of a philoſopher, was ſupplanted

planted in the popular eſteem by Heraclides, a Syracuſan exile, and obliged to make his retreat to Leontium. The inhabitants of Syracuſe were ſoon after reduced to diſtreſs by an armament ſent againſt them by Dionyſius; and a deputation was ſent to Dion, imploring his aſſiſtance. The philoſopher, burying in oblivion the ſlight he had received, and anxious only for the welfare of the ſtate, determined to make an attempt for its deliverance. Accordingly, he marched at the head of a body of troops, who declared their readineſs to follow him to death or victory, and found the city in the laſt extremity of deſolation and terror. Having pardoned the machinations of Heraclides and his adherents, who ſurrendered themſelves into his hands, he gained poſſeſſion of the citadel, and entered it in preſence of the applauding citizens. At the gate he was met by his ſiſter, leading his ſon and his wife Arete. The two former were embraced by him, while the latter ſtood by unnoticed, and diſſolved in tears. At length his tenderneſs was awakened, and, embracing her, he ſent her with his ſon to his houſe. Having eſtabliſhed the Syracuſans in poſſeſſion of their citadel, he diſmiſſed his guards, and retired to the condition of a private citizen. As ſoon as public tranquillity was reſtored, inteſtine factions revived. Heraclides was among the foremoſt of the malcontents, and Dion was perſuaded to aſſaſſinate him. This fatal deed robbed him of all mental peace, and his imagination was henceforth haunted with avenging furies. Having loſt his ſon by a premature and voluntary death, an Athenian, who was his intimate friend, formed a conſpiracy againſt his life. Burſting into his houſe, the traitor ſeized his perſon, and, whilſt Dion ſtruggled, his murderers, being unprovided with weapons, could not diſpatch him, till they were ſupplied through a window with a dagger. The death of Dion happened about the year 354 B. C. in the 55th year of his age. His ſiſter and wife, and a poſthumous infant of which his wife was delivered, were ſoon after put to death. The Syracuſans afterwards cheriſhed his memory as their deliverer, and honoured him with a public monument. Plut. Vit. Dion. Rollin's Anc. Hiſt. vol. iv.

Dion Cassius Cocceianus, was a native of Nice, in Bithynia, and the ſon of Apronianus, who was prefect of Bithynia at the acceſſion of Adrian. Dion was a ſenator of Rome in the reign of Commodus, and entruſted with ſeveral governments and poſts of dignity under the ſucceeding emperors. He was twice conſul; the ſecond time as colleague to the emperor Alexander Severus, A. D. 229. His rigorous diſcipline, when he commanded the Pannonian legions, excited a tumult and a combination againſt him, which endangered his life. But he retired from Rome, and paſſed the greater period of his conſulſhip in Campania. He afterwards returned to his native country, and finiſhed his days in tranquillity. Twenty-two years of his life were devoted to the compoſition of a Roman hiſtory in the Greek language, comprehending, in eight books, the whole period from the origin of the Roman ſtate to his own times. Ten years were employed in collecting materials, and twelve more in digeſting and arranging them. To this work, as he informs us, he was impelled by a viſion, which occurred to him the night after he had received the emperor Severus's thanks for a treatiſe which he had compoſed on the preſages that had announced the elevation of that prince. This circumſtance leads us to conclude, that he was not only ſuperſtitious, but inclined to adulation; and, indeed, his hiſtory is evidently partial to Cæſar and his party, whilſt it abuſes Cicero, Brutus, Seneca, and other patriots. His ſtyle, however, is clear and eaſy, and he has interſperſed a variety of judicious reflections. Of the 80 books, the firſt 54 and and part of the 55th are loſt. The 25 following are extant, but the latter ſix in an abridged ſtate; the laſt 20 are alſo loſt, except a few fragments. We have, however, an epitome of his work from the time of Pompey to the end of it in the reign of Severus, which was made by John Xiphilinus, nephew to the patriarch of Conſtantinople. Dion's hiſtory, notwithſtanding its defects, is juſtly admired, and Xiphilinus's epitome is well eſteemed. In ſome places we find fragments of Dion himſelf; and the epitome often repreſents Dion in his own words. Dion's hiſtory is ſuppoſed to have been publiſhed ſoon after the year 230. In Dion's hiſtory we have a ſhort and defective account of the ſiege and capture of Jeruſalem, which affords a teſtimony to the ruin of the temple and city, and the conqueſt of Judæa under Titus and Veſpaſian. We have, likewiſe, in the hiſtory of Domitian, an atteſtation to the progreſs of Chriſtianity, and the ſufferings of its profeſſors. It appears that it had got footing in the imperial family. Clement ſuffered death on account of it; and Domitella his wife was baniſhed to a remote and inſalubrious iſland, whither perſons were wont to be ſent for ſtate crimes, or other like offences. Another paſſage in Dion's hiſtory confirms the ſuppoſition of the ſeverity of Domitian's perſecution, though it was not long, and leads us to conclude, that the perſecution did not ceaſe till after the beginning of Nerva's reign. We have alſo an account of the ſhower by which Marcus Antoninus and his army were ſaved in Germany. The beſt editions of Dion Caſſius are thoſe of Leunclavius, Hanau, fol. 1606, and of Reimarus, Hamburgh, 2 vols. fol. 1750. Crevier's Hiſt. Emp. vol. viii. Lardner's Works, vol. viii.

Dion, or *Dium*, in *Ancient Geography*, a promontory placed by Ptolemy in the northern part of the iſle of Crete. —Alſo, a town of Greece, in Eubœa.—Alſo, a town of the Decapolis, between Pella and Gadara. Ptol.—Alſo, a town placed by Strabo and Herodotus in Epirus.—Alſo, a town of Greece, in Macedonia, ſituated north of mount Olympus, and near it, where the games were celebrated.—Alſo, a town of Italy.—Alſo, a town of Aſia, in Piſidia.—Alſo, a town of Thrace, near mount Athos.—Alſo, a town of Aſia, in Cœloſyria. Steph. Byz. ſays that it was near Pella, and built by Alexander. Ptolemy diſtinguiſhes Pella from Dion.

DIONÆA, in *Botany*, (a name of Venus, from her mother Dione. "*Sacra Dionæ matri, Diviſque ferebam*," ſays her ſon Æneas, Virg. Æn. 3. 19. In its botanical application, of which Solander and Ellis were the authors, it may be underſtood as alluding to the elegance and delicacy of the flowers which rival thoſe of Linnæus's favourite *Trientalis*.) Venus's Fly-trap. Ellis in Act. Nov. Upſal. v. 1. 98. t. 8. Ejuſd. Monogr. 38. t. 1. Linn. Mant. 2. 151. Schreb. 288. Willd. Sp. Pl. v. 2. 574. Mart. Mill. Dict. v. 2. Juſſ. 431. Claſs and order, *Decandria Monogynia*. Nat. Ord. *Gruinales*, Linn. "Uncertain," Juſſ. Undoubtedly a-kin to *Droſera*, and therefore to the *Capparides* of Juſſieu.

Gen. Ch. *Cal.* Perianth of five ovate-oblong, acute, ſpreading, permanent leaves. *Cor.* Petals five, equal, obovate, concave, longer than the calyx, with numerous pellucid ribs in their lower part. *Stam.* Filaments ten, equal, awl-ſhaped, ſpreading, ſhorter than the petals; anthers roundiſh, ſmall, their pollen three-lobed. *Piſt.* Germen ſuperior, roundiſh, depreſſed, furrowed; ſtyle thread-ſhaped, ſhorter than the filaments; ſtigma depreſſed, fringed. *Peric.* Capſule of one cell, furrowed. *Seeds* numerous, minute, nearly ovate, affixed to the "bottom of the capſule." Ellis.

Eſſ. Ch. Calyx of five leaves. Petals five, equal. Capſule ſuperior, furrowed, of one cell. Seeds numerous, affixed to the baſe of the capſule. Stigma fringed.

The

The only known ſpecies is D. *Muſcipula*, figured by Ellis in the places above cited, copied in Shaw's Nat. Miſc. t. 40. But Venten. Jardin de la Malmaiſon, t. 29. and Sims in Curt. Mag. v. 20. t. 785, are original figures. It grows in the ſwamps of North Carolina, lat. 35° north, and was ſent in a dried ſtate by John Bartram to Peter Collinſon, who, in 1765, ſent the ſame to Ellis. Solander communicated a ſpecimen to Linnæus, from which, and Ellis's paper, the characters in the ſecond *Mantiſſa* were drawn up. Mr. William Young ſent living plants to Kew in 1768, ſince which time others have frequently been brought to England, where they bloſſom one ſeaſon in a ſtove, by means of conſiderable heat and moiſture, but ſeldom ſurvive our winters. The great ſingularity of the plant conſiſts in its leaves, which are radical, numerous, ſpreading on the ground; obovate, each terminated by an orbicular appendage, half an inch or more in breadth when expanded, but compoſed of two hemiſpherical lobes, ſtrongly toothed at their outer edge, coloured and glandular within. On the inſide of each lobe ſtand about three highly irritable erect briſtles, which, when touched, cauſe the two lobes to fold together like a rat-trap, impriſoning inſects, no doubt that their putrifying bodies may adminiſter an air wholeſome to the plant, which theory, recent obſervations on *Sarracenia*, *Droſera*, and *Nepenthes* confirm. See Sm. Introd. to Botany, 195—198. The roots of the *Dionæa* are deſcribed as ſcaly and perennial. The flower-ſtalk is ſolitary, radical, a ſpan high, bearing a corymbus of very elegant ſnow-white flowers, ſomewhat reſembling, in general aſpect, thoſe of the *Parnaſſia*, the petals moreover being, like theirs, ſtriped with pellucid parallel veins. Our knowledge of the fruit is imperfect, but it ſeems very much to accord in general ſtructure with thoſe of *Parnaſſia* and *Droſera*, at leaſt ſo as to ſtamp them all of the ſame natural order, while other particulars approach theſe plants to *Saxifraga*, as hinted in Engl. Bot. v. 2. t. 82. The theory of botanical affinities is too much a ſcience of conjecture to juſtify dogmatical concluſions, and any univerſal ſyſtems founded upon it can as yet be but artificial and incomplete. Such attempts, however, conducted with due modeſty, are laudable, and muſt in the end lead to ſome truths. S.

DIONÆA, in *Gardening*, compriſes a plant of the low growing herbaceous perennial exotic kind; the Venus's Fly-trap, D. *muſcipula*.

It riſes in a ſimple ſtem to the height of about ſix inches, which ends in a ſpike of milk-white flowers. It has two lobes at the upper joint of the leaf, which conſtitute a ſort of trap, hence its name.

Method of Culture.—This is a plant which is increaſed by ſowing the ſeed obtained from its native ſituation in pots of light moiſt mould which ſhould be plunged in a moderate hot bed, and when the plants have acquired ſome growth, they ſhould be removed into ſeparate ſmall deep pots filled with bog earth, dew water, and ſhade, being given till they become well rooted.

The plants afterwards require to be placed in a frame or green-houſe, ſo as to be protected from the full ſun during the ſummer heat, and have a free air, with proper waterings; but in the beginning of autumn, placed in the green-houſe, ſo as to be guarded from the effects of froſt being very moderately watered at that period.

Theſe are plants which are of the ſenſitive kind, affording variety among others of the exotic green-houſe ſorts.

DIONE, in *Mythology*, a ſea nymph, the daughter of Ocean and Thetis, and the mother of Venus by Jupiter.

DIONE, in *Zoology*, a ſpecies of COLUBER.

DIONIA, in *Ancient Geography*, a town of the iſland of Cyprus.

DIONIS, PETER, in *Biography*, educated to the practice of ſurgery, in which he acquired conſiderable fame; became firſt known by being appointed reader of the lectures in anatomy and ſurgery in the royal gardens at Paris, inſtituted by Lewis XIV. This procured him, in 1680, the appointment of ſurgeon in ordinary to the queen, the dauphineſſes, and the royal children, which offices he held, with great credit, to the 16th of December, 1718, the time of his death. His firſt publication contained the hiſtory of a woman, who was ſuppoſed to have died in conſequence of a rupture of the uterus. She was only in the ſixth month of her pregnancy. On opening the body, there appeared, the author ſays, to be two uteri, one of which was ruptured. But as the woman was only in the ſixth month of her pregnancy, it is probable the fœtus had never reached the uterus, but was detained in one of the Fallopian tubes, which gave way, not bearing to be diſtended to ſuch a ſize as would contain a full-grown fœtus. We have two caſes of ruptured Fallopian tubes recorded; one by De Graaf, and the other by Cyprianus: but there are no caſes of ruptured uteri occurring at ſo early a period of pregnancy. This was publiſhed in 1683. In 1690 he publiſhed "Anatomie de l'homme, ſuivant la circulation du ſang, et les nouvelles decouvertes," 8vo.; an uſeful epitome, containing all that was then known on the ſubject. It was well received, and frequently reprinted. It was tranſlated, in 1718, into the Tartar language, by order of Cam-hi, the emperor of China, for the benefit of his ſubjects. His next work, which firſt appeared in 1707, was "Cours d' Operations de Chirurgie demontreé, au Jardin Royal de Paris," 8vo. This has been reprinted ſtill more frequently than the former work, and has been tranſlated into nearly all the modern languages. Heiſter gave an edition of it in Latin, with notes, and it ſtill retains a certain degree of credit. In 1709, he gave "Diſſertation ſur la mort ſubite, avec l' hiſtoire d'une fille cataleptique," 12mo.; and, in 1718, "Traite general des accouchmens," 8vo. This alſo has been tranſlated into moſt modern languages, though it contains little more than an abridgment of the practice of Mauriceau, and is now almoſt entirely unnoticed. Hall. Bib. Chir. Eloy. Dict. Hiſt.

DIONYSI PROMONTORIUM, or *Civitas*, in *Ancient Geography*, a promontory or town, ſituated in the ſouthern part of the iſland of Taprobana, according to ſeveral copies of Ptolemy.

DIONYSIA, an iſland of the Mediterranean ſea, over-againſt the coaſt of Etolia.—Alſo, an iſland of the ſame ſea, over-againſt the coaſt of Lycia, in Aſia Minor. Pliny ſays that it was ſometimes called *Caretha*.—Alſo, an epiſcopal town of Aſia, under the metropolis of Boſtra.—Alſo, a town of Greece, in Bœotia, ſaid to have been built by Bacchus.—Alſo, a town of Italy.

DIONYSIA, or *Dionyſiaca*, ſolemn feaſts, held among the ancients, in honour of Bacchus.

The word is formed from the Greek Διονυσια, of Διονυσος, *Bacchus*; and that of Διος, the genitive of Ζευς, *Jupiter*, and *Nyſa*, a city in Egypt, on the frontiers of Arabia, where Bacchus is ſaid to have been educated by the nymphs.

The Dionyſia are the ſame with what are otherwiſe called Orgia, and by the Romans Bacchanalia and Liberalia.

There are divers feſtivals under the denomination of Διονυσια, *Dionyſia*; but the chief were two; *viz.* 1. The ancient, αρχαιωτερα, probably the ſame with μεγαλα, or the greater Dionyſia; ſometimes alſo called, by way of eminence, Διονυσια, without any other addition, as being the moſt celebrated of all Bacchus's feſtivals at Athens, where it was held in the month of Elaphebolion. This feſtival was celebrated by the Athenians with extraordinary magnificence; tragedies and comedies

comedies were then exhibited in the theatre; and hymns in honour of Bacchus, accompanied with flutes, were chaunted by the chorus, in the Odeum. On this occaſion each of the 10 Athenian tribes appointed a choragus, whoſe office is particularly deſcribed under the article CHORAGUS. 2. The new, Νεωτερα, probably the ſame with μικρα, or the leſſer Dionyſia, held in autumn, as a ſort of preparation to the greater. Some will have this the ſame with Διονυσια ληναια, ſo called from ληνος, a *wine-preſs*, and place it in the month Lenæon.

Several days of the year were dedicated to the worſhip of Bacchus. The city, the harbour of Piræus, the country, and the neighbouring towns, alternately re-echoed with his name. The whole city has on this occaſion been in a ſtate of complete intoxication. Bacchanals and bacchanalian nymphs, crowned with ivy, fennel, and poplar, danced and howled through the ſtreets with convulſive agitations, and invoked Bacchus with barbarous acclamations. They have torn the raw entrails of the victims with their teeth and nails, ſqueezed ſerpents in their hands, interwove them in their hair, twiſted them round their bodies, and by ſuch extravagancies attracted the attention of the terrified multitude. Similar ſcenes were exhibited at a feſtival which was celebrated on the firſt appearance of ſpring. The city was then filled with ſtrangers, who repaired thither in crowds, to bring the tribute of the iſlands ſubjected to the Athenians, to ſee the new pieces preſented at the theatre, and to be preſent at the games and public ſhows; but, above all, at a proceſſion which repreſented the triumph of Bacchus. In this the ſame retinue is exhibited with which that god is ſaid to have been attended when he made the conqueſt of India: men, who perſonated ſatyrs, others who repreſented the god Pan; ſome dragging goats along to ſacrifice them; others mounted on aſſes in imitation of Silenus; others diſguiſed like women; others again carrying obſcene figures, ſuſpended on long poles, and ſinging the moſt licentious hymns: in fine, all ſorts of perſons, of both ſexes, moſt of them clad in the ſkins of fawns, concealed under maſks, crowned with ivy, either drunk or feigning to be ſo, mingling their uninterrupted ſhouts with the ſound of inſtruments; ſome agitating their bodies like madmen, and abandoning themſelves to all the convulſions of fury; others executing regular and military dances, but holding vaſes inſtead of bucklers, and throwing thyrſi, in the manner of darts, with which they ſometimes menaced and inſulted the ſpectators. In the midſt of theſe bands of furies, the choruſſes deputed by the different tribes advanced in the moſt perfect order; and a number of young women, of the moſt diſtinguiſhed families of the city, walked with downcaſt eyes, decked out in all their ornaments, and bearing on their heads the ſacred baſkets, which, beſides offerings of the choiceſt fruits, contained cakes of different forms, grains of ſalt, ivy leaves, and other myſterious ſymbols.

The roofs of the houſes, which were in the form of terraces, were covered with ſpectators, and eſpecially women, moſt of them with lamps and torches, to light the proceſſion, which almoſt always began its march at night, halting in the ſquares and public places, to make libations, and to offer up victims in honour of Bacchus. The day was conſecrated to different games. The company repaired early to the theatre, either to be preſent at the competitions in muſic and dancing between the choruſſes, or to ſee the new pieces, which the poets had prepared for the occaſion. The firſt of the nine archons preſided at theſe feſtivals; the ſecond at other ſolemnities; and both had ſubordinate officers to relieve them in their functions, and alſo guards to drive all perſons from the theatre, or other ſpectacles, who occaſioned any diſturbance. As long as theſe feſtivals continued, the leaſt violence done to a citizen was criminal, and no creditor was allowed to proſecute his debtor. All crimes and diſorders committed at this time were ſeverely puniſhed on the ſucceeding days. Anacharſis, vol. ii.

On occaſions of this kind, the Heathens worſhipped with divine honour thoſe parts of the body, which are the inſtruments of exciting and gratifying the moſt impure paſſions. The figures of them, as we have obſerved above, were carried about in ſome of their ſacred proceſſions, to which hymns were ſung, and religious veneration paid. Concerning the obſcenities in their ſacred rites and ceremonies, Arnobius, who had himſelf been a learned Pagan, treats largely. (Adverſ. Gent. l. v. p. 168, 169, &c. Ed. Varior. Lugd. Bat. 1651.) to which may be added what Clemens Alexandrinus relates concerning the ſacred cheſt or coffer of Bacchus, and its impure contents, which were propoſed to veneration. (Clem. Alex. Protrept. p 16. Ed. Potter.) See alſo what Auſtin ſays from Varro, which delicacy forbids us to tranſlate. "De turpitudine ſacrorum quæ Libero celebrantur. In Italiæ compitis quæ dicit (Varro) ſacra Liberi celebrata cum tantâ licentiâ turpitudinis, ut in ejus honorem pudenda virilia colerentur. Nam hoc turpe membrum, per Liberi dies feſtos cum honore magno plaſtellis impoſitum, priùs vere in compitis, et uſque in urbem poſtea vectabatur. In oppido autem Lavinio Libero totus menſis tribuebatur, cujus diebus omnis verbis flagitioſiſſimis uterentur, donec illud membrum per forum tranſvectum eſſet, atque in loco ſuo quieſcerit. Cui membro inhoneſto matrem familias honeſtiſſimam palàm coronam neceſſe erat imponere." Auguſtin. De Civ. Dei, l. vii. c. 21, p. 136. Ed. Bened.

DIONYSIACA, in *Antiquity*, was a deſignation given to plays and all manner of ſports acted on the ſtage; becauſe play-houſes were dedicated to Dionyſius, *i. e.* Bacchus and Venus, as being the deities of ſports and pleaſure. Potter, Archæol. Græc. lib. i. cap. viii. tom. i. p. 41.

DIONYSIADES INSULÆ, in *Ancient Geography*, iſlands mentioned by Diodorus Siculus, and placed by him in the vicinity of that of Candia, in the gulf *Didymus*.

DIONYSIAN, or VICTORIAN PERIOD. See CYCLE, and PERIOD.

DIONYSIANA, in *Ancient Geography*, a town of Africa, in the Bizacian territory.

DIONYSIAS, a town of Egypt, ſituated near the lake Mœris.

DIONYSIAS, in *Botany*, from Διονυσος, *Bacchus*, is not only an appellation of the Ivy, ſacred to him, but has been given to the *Hypericum Androſæmum*, or Tutſan, by ſome writers, who are generally conſidered, in that inſtance at leaſt, as incorrect.

DIONYSII PROMONTORIUM, in *Ancient Geography*, a mountain of Spain, on the ſea of Iberia, acccording to the Argonautics of Orpheus.

DIONYSIUS I. in *Biography*, king of Syracuſe, was raiſed to that high rank, from the ſtate of ſimple citizen. He was ſon-in-law to Hermocrates, who, having been baniſhed by an adverſe party, attempted to return by force of arms, and was killed in the action. Dionyſius was dangerouſly wounded, but he recovered, and was afterwards recalled. In time he procured himſelf to be nominated one of the generals, and under pretence of raiſing a force ſufficient to reſiſt the Carthaginians, obtained a decree for recalling all the exiles. He was ſoon called to take the chief command. His firſt act was to double the ſoldier's pay, and pretending that his life was in danger, he was allowed a body guard, which he took care to ſelect from thoſe moſt devoted to his ſervice. His courſe was now clear; and in the 25th year of his

age about 404 B. C. he aſſumed the title of king of Syracuſe. His reign was not without trouble: in an expedition againſt the Carthaginians, he was deſerted by his own cavalry, who fled back to the city, and made themſelves maſters of the citadel and of his treaſures. Apprized of their plans, he followed them with great celerity, got poſſeſſion of the citadel, and took a ſpeedy and ſevere revenge. He now made peace with the Carthaginians, and employed himſelf in fortifying the city, after which he made an expedition againſt ſome of the free ſtates of Sicily; and in time he became maſter of the whole iſland, and then ſet about expelling the Carthaginians from all their remaining poſſeſſions in Sicily. With this view he ſpared no expence; inviting all the beſt artificers from Greece and Italy, whom he treated with a liberality truly worthy of his high rank. He fitted out a great fleet and rendered himſelf very popular among his own ſubjects. War was now declared againſt the Carthaginians, and carried on for ſome years with various ſucceſs: during the conteſt, Polyxenus, who had married Theſta, the ſiſter of Dionyſius, declared againſt the king, and when he was beaten and obliged to retire, Dionyſius ſent for his ſiſter, inſiſting upon her diſcovering whither Polyxenus had fled. "Do you ſuppoſe me," ſaid Theſta with a noble mind, "ſo bad a wife as not to have accompanied my huſband had I been aware of his departure? If I had been acquainted with his deſign, I ſhould have never informed you of it, but ſhould have ſhared all hazards with him, and have thought myſelf more honoured in being called the wife of Polyxenus the exile, than ſiſter of Dionyſius the tyrant." The king forgave her freedom, and the Syracuſans ſo much honoured her conjugal fidelity, that after the abolition of the tyranny, they continued, during her life, to treat her with all the honours of her rank, and beſtowed a public funeral upon her at her deceaſe. The Carthaginians were at length ſo much reduced by defeats and ſickneſs, that they were glad to obtain permiſſion to quit the iſland. Dionyſius afterwards carried his arms into Italy, beſieged and took Rhegium, and ſold all his captives for ſlaves. His conduct towards Phyto, the commander, was worthy only of a cruel tyrant, a character which in many reſpects he deſerved, as well for his actions, as for the mode by which he attained the ſovereignty: the ſon of Phyto he cauſed to be thrown into the ſea, and the father he firſt treated with every indignity, and then put to death. Dionyſius was not leſs ambitious of being eſteemed learned, than he was of being poſſeſſed of the ſupreme power. He wiſhed to be regarded as a poet, an honour which no doubt was readily conferred upon him by ſervile flatterers, but Philoxenus ſpoke freely of the merit of the verſes of his royal maſter; and as a reward for his integrity, was committed to priſon. Dionyſius, however, liberated him the next day, and then inviting him to a ſplendid entertainment, read ſome other verſes, which he thought would not fail of the poet's approbation: in this however he was diſappointed. Philoxenus, when he had heard the lines, turned to the guards, and deſired them to carry him back to the priſon: the king, no doubt, mortified at the incivility which was offered him, had the moderation and good ſenſe to pardon it. Dionyſius next ſent his brother in his own name, and with his own productions, to contend at the Olympic games for the prize awarded to the beſt written poetry; the brother, it was admitted, did his part; but the verſes were received with the utmoſt ridicule: and Lyſias, the orator, pronounced an harangue, proving that it was diſhonourable for Greece to ſuffer an impious tyrant to ſhare in the ſolemnities of a ſacred entertainment. Dionyſius, however, made a ſecond attempt, and meeting with no better ſucceſs, he fell into a phrenetical melancholy. He vented his firſt rage on his own friends, and then attempted to divert his chagrin by a public war, which proved unſucceſsful, and he was obliged to conclude a peace on very unfavourable terms. Dionyſius, after the death of his firſt wife, married two others at once, *viz* Doris, a Locrian, and Ariſtomache, the ſiſter of Dion: he treated them with impartiality, and had children by both. His relation Dion reproved him with moderation, and, in order to improve his mind and temper, perſuaded him to invite Plato to his court; but the diſcourſes of the philoſopher were ill adapted to the irritated mind of the tyrant, and he was ſent back in diſgrace. It is even ſaid that he directed the owner of the veſſel to ſell Plato for a ſlave, obſerving that according to his doctrine, no injury could be done him, ſince a virtuous man muſt be happy in every ſtate: ſuch was the apology which he was willing to offer for the injuſtice that he was anxious to commit. As he advanced in years, he became the moſt ſuſpicious of tyrants: he confided in no one: the moſt intimate of his wives' relations, and their neareſt friends, were never permitted to enter the palace without being previouſly ſearched, and the king himſelf ſlept in a bed chamber ſurrounded by a deep ditch, with a drawbridge. It is recorded of Dionyſius that he obliged the ſervile courtier Damocles to partake of a ſplendid feaſt, while a naked ſword was ſuſpended by a ſingle hair over his head. In the year 366 B. C. a tragedy of his was acted, and to it was awarded the prize: this ſo elated the king, that he offered a ſolemn ſacrifice, feaſted all his ſubjects, and drank himſelf ſo much to exceſs, as to be the cauſe of his death, which happened in the thirty-eighth year of his reign. Univer. Hiſt.

Dionysius II. ſon of the preceding, ſucceeded peaceably to his authority, but he was ſoon plunged into the debaucheries of a court, and it required all the influence of his uncle Dion, aided by the leſſons of Plato, to recal him to ſobriety. He then ſeemed to imbibe the true principles of philoſophy, and to enter ſo much into their ſpirit, as to conſider the cares of government a curſe rather than a bleſſing. The courtiers gained an aſcendancy over the young king, and ſucceeded in driving from his preſence Dion and Plato. The latter was exhorted to return, to which he conſented, and Dionyſius received him in the moſt honourable manner: their friendſhip did not long continue, and Plato again left the court, upon which Dionyſius abandoned himſelf to every ſpecies of exceſs and tyranny. While Dionyſius was abſent in Italy, Dion landed in Sicily, took poſſeſſion of Syracuſe, from which the king was unable to expel him till after the aſſaſſination of Dion, and Sicily itſelf had been the prey of different factions and tyrants. In the year 350 B. C. he re-aſcended the throne, but his paſt misfortunes did not produce any real effect on the mind of the monarch: the evils which he had ſuffered in his own perſon from the violence of party, exaſperated his temper, and rendered him more a tyrant. At length driven to retirement by Timoleon, he went to Corinth, where he kept low company, and indulged in groſs debauchery. He took upon himſelf to direct the performances of the theatre, and diſplayed ſome ſkill in muſic. Some writers have aſſerted that he was obliged, for a maintenance, to open a ſchool at Corinth; but this is not mentioned by Plutarch, and is probably not entitled to credit. Neither the time nor the place of his death is known. In his fallen ſtate he was liable to the reproaches and ſarcaſms of the witty: to one who aſked what he had gained by the wiſdom of Plato, he replied, "The ability to bear as I do this change of fortune." Plutarch. Univer. Hiſt.

Dionysius of Halicarnaſſus, an hiſtorian and critic, ſon of Alexander, was a native of Halicarnaſſus, in Caria.

Caria. He came to Rome B. C. 30, and paſſed more than twenty years in that capital. Here he employed himſelf in ſtudying the Latin language, in converſing with men of learning, and in carefully peruſing the ancient Roman hiſtorians. From their works he compiled his "Roman Antiquities," in which the hiſtory of the city was brought down to the firſt Punic war. This work originally conſiſted of twenty books, of which eleven only have come down to us. Dionyſius wrote alſo on rhetorical and critical ſubjects, and his "Compariſons of ſome Ancient Hiſtorians" and "Treatiſe on the Structure of Language," are well known to the moderns. The ſtyle of this writer is flat and languid, but he is regarded as an accurate hiſtorian, and judicious in his narratives. Moreri.

Dionysius, called the *Areopagite*, from his being a member of the court of Areopagus, at Athens, was probably born in that city, and was converted to Chriſtianity by St. Paul's preaching. (See Acts, xvii. 34.) His literary acquirements at Athens and at Heliopolis, in Syria, are ſaid to have been conſiderable, and we may infer from the ſtation which he occupied that his character was reſpectable. Tradition reports that he was the firſt biſhop of Athens, appointed to that office by the apoſtle Paul; and that he was one of the early Chriſtians, who ſuffered martyrdom, probably under Domitian. Several works have been aſcribed to Dionyſius, which were printed at Cologne in the year 1536, and which have been frequently reprinted with various commentaries. The moſt complete editions are thoſe of Antwerp, in 1634, and of Paris, in 1644, both in two volumes folio. It is now, however, the general opinion of learned men, that they are ſpurious, though they differ in opinion concerning the time when they were written. The opinion moſt generally received is, that they were written in the latter part of the fifth, or the beginning of the ſixth century. James Baſnage aſſerts, that the author of theſe works mentions no books of the Old Teſtament but thoſe of the Jewiſh canon; and it it is plain that one of thoſe books is the Song of Songs. Daillé ſays, that he omits no ſacred book, either of the Old or New Teſtament; however "the beloved diſciple" alone is expreſsly mentioned. It is manifeſt, that the author received the Revelation; and it is probable, that he thought St. John's Goſpel to be the laſt written book of the New Teſtament, it being mentioned laſt, and next after the book of Revelation. Fab. Bib. Gr. T. v. Cave's H. L. vol. i. Lardner's Works, vol. ii. iii. and v.

Dionysius, biſhop of Corinth, flouriſhed under the emperors Marcus Antoninus and Commodus, about the year 170. Some have aſſerted, but without ſufficient authority, that he was a martyr. St. Jerom repreſents him as a man of great eloquence and induſtry, and he appears to have been actuated in a very eminent degree by a truly Chriſtian ſpirit. Deſirous of extending his uſefulneſs beyond the limits of his own eccleſiaſtical charge, he addreſſed epiſtles to Chriſtian churches in different provinces of the Roman empire, with a view of confirming them in the faith, and guarding them againſt noxious errors. Of theſe epiſtles we have remaining only ſome fragments cited by Euſebius; but theſe ſeem to evince the genuineneſs of the Chriſtian ſcriptures, and to pourtray the judgment, candour, and peaceable ſpirit of the author. Cave's H. L. vol. i. Lardner's Works, vol. ii.

Dionysius, biſhop and probably native of Alexandria, ſucceeded Heraclas in the chair of the catechetical ſchool of that city, A.D. 231 or 232, and upon his death was choſen biſhop in his room, A.D. 247 or 248. He died in the 12th year of the emperor Gallienus, in the year of Chriſt 264 or 265. Dionyſius was deſcended from a Gentile family of rank and wealth; and after his converſion to the Chriſtian faith, became a diſciple of Origen, and was afterwards numbered among his moſt diſtinguiſhed ſcholars. The period of his epiſcopate was peculiarly trying and difficult, but ſuch was his prudence, that he conducted himſelf in ſuch a manner as to cloſe life with reputation. During this period there happened the two perſecutions of Decius and Valerian, beſide a peſtilence that ravaged the whole Roman empire, and other public calamities, together with ſome private commotions, in which Alexandria was concerned. It was alſo at this time that the Chriſtian church was agitated by the controverſies about Novatianiſm, the Millennium, the baptiſm of heretics, and the doctrine of the Trinity, in all which Dionyſius ſignalized himſelf by his learning, zeal, moderation, and prudence. Soon after Decius's edict of perſecution, which was publiſhed at Alexandria in the beginning of the year 250, Dionyſius was ſeized by order of Sabinus, prefect of Egypt, and committed to cuſtody at Tapoſyris, a ſmall village in that part of Egypt called Mareotis. But being reſcued from this confinement, he retired to a deſert part of Libya till the termination of this perſecution, when he returned to his charge at Alexandria ſome time in the year 251.

Soon after the commencement of the perſecution under Valerian and his ſon Gallienus, before the end of the year 257, Dionyſius was ſummoned before Emilian, then prefect of Egypt; who required him to renounce the Chriſtian religion; but to this authoritative mandate the biſhop replied, without heſitation, that *we ought to obey God rather than man* (Acts, v. 29.), and aſſured the prefect, that he was a worſhipper of the one God, and could worſhip no other, nor could he ever ceaſe to be a Chriſtian. Upon which he ordered Dionyſius and his aſſociates to a place called Cephro, in Libya, under a ſtrict prohibition that they ſhould not hold any aſſemblies. During his exile, he retained a tender affection and concern for his people, and exerciſed his miniſtry among thoſe who were his companions in tribulation. In this ſtate of baniſhment he continued about two or three years; and in the year 261, he returned to his people at Alexandria, among whom he officiated to their great ſatisfaction and profit. But the peace of this city was of ſhort duration; for it was again afflicted with ſedition and war, and then with peſtilence. In theſe diſtreſſing ſcenes, Dionyſius exhibited an admirable example of fortitude, piety, and humility, and of zeal in promoting the edification and tranquillity of the Chriſtian church. Of the numerous epiſtles and treatiſes which were written by him, we have remaining only one entire epiſtle, and conſiderable fragments of others preſerved by Euſebius. In the controverſies of his time, Dionyſius ſeems to have taken an active part. He ſtrongly oppoſed the opinion of Novatian on the ſubject of repentance, and the treatment of lapſed Chriſtians. He was alſo adverſe to the groſs notions of the millennium, that prevailed in ſome parts of Egypt; and he endeavoured to appeaſe the contentions that ſubſiſted between Stephen biſhop of Rome, and Cyprian biſhop of Carthage; and the letters which he wrote on this occaſion manifeſt an excellent ſpirit of candour and Chriſtian charity. He wrote alſo againſt the doctrine of Sabellius concerning the Trinity, and againſt Paul of Samoſata, whoſe peculiar opinions will appear under their reſpective articles. Dionyſius's own opinion, with regard to the Trinity, ſeems to have been much the ſame with that of Arius. Euſebius's E. H. l. vi. and vii. Cave's Hiſt. vol. i. Fab. Bib. Græc. T. v. Lardner's Works, vol. iii.

Dionysius, pope, or biſhop of Rome, was advanced from the office of preſbyter to the epiſcopal dignity in this city, July 22, A.D. 259, and died December 26th, A.D. 269.

269. About the commencement of his epiſcopate, in the year of our Lord 260, or 261, the Chriſtians at Cæſarea, in Cappadocia, were reduced to great diſtreſs by the invaſion of ſome barbarous people; upon which this good biſhop wrote them a letter of ſympathy and comfort, and ſent ſome perſons to redeem ſuch of the brethren as had been taken captive. This benefit was long held in grateful remembrance at Cæſarea. Dionyſius was a writer in the Sabellian controverſy, and correſponded with his name-ſake of Alexandria on this ſubject. A large fragment of what he wrote on this point remains cited in a work of Athanaſius. He alſo addreſſed a letter to the biſhop of Alexandria upon the queſtion of the baptiſm of heretics. The decretal epiſtles that have been aſcribed to him are allowed to be ſpurious, nor does any thing of his genuine writings remain beſide the fragments above-mentioned. Euſebius and Baſil repreſent him as a perſon of great learning and perſonal merit. From the fragments that remain of his writings, it ſufficiently appears that he concurred with other Chriſtians of that time in acknowledging the divine ſcriptures, contained in the Old and New Teſtaments, to be the rule of faith by which all doctrines were to be tried. Euſebius's E. H. l. vii. c. 7. Cave's H. L. Lardner's Works, vol. iii.

Dionysius, ſurnamed *Exiguus*, or the Little, on account of his ſhort ſtature, was a native of Scythia, flouriſhed under Juſtinian towards the beginning of the ſixth century, and died, according to Cave, before the year 556, or, according to Blair's Tables, in the year 540. He was a monk and abbot of Rome, and an intimate friend of Caſſiodorus, who extols his learning and character. This writer informs us that he was a complete maſter of the Greek and Roman languages, that he had diligently ſtudied the ſcriptures, and that he was eminently diſtinguiſhed by a combination of great wiſdom, learning, and eloquence, with the moſt amiable virtues. His works, recited by Cave (ubi infra) were numerous; and he is ſaid to have been the author of the vulgar Chriſtian *epocha* (which ſee), and to have invented the *Cycle* of Eaſter (which alſo ſee), aſcribed by others to Victor, or Victorinus. Cave's H. L. vol. i. p. 513.

Dionysius, a Greek poet and muſician, author of the words and muſic of three hymns, of which the firſt is addreſſed to Caliiope, the ſecond to Apollo, and the third to Nemeſis. Of theſe the muſic has been preſerved and publiſhed by Dr. Fell, biſhop of Oxford, in 1672. This precious manuſcript, which was found in Ireland, among the papers of the famous archbiſhop Uſher, was bought, after his deceaſe, by Mr. Bernard, fellow of St. John's college, who communicated it to the editor, together with remarks and illuſtrations by the reverend Mr. Edmund Chilmead, of Chriſt-church, who likewiſe reduced the ancient muſical characters to thoſe in common uſe. It appears by the notes, that the muſic of theſe hymns was compoſed in the Lydian mode, and diatonic genus.

Vincenzo Galilei, father of the great Galileo, firſt publiſhed theſe hymns, with their Greek notes, in his "Dialogues upon Ancient and Modern Muſic," printed at Florence, 1581, folio. He aſſures us, that he had them from a Florentine gentleman, who copied them very accurately from an ancient Greek manuſcript, preſerved in the library of cardinal St. Angelo, at Rome, which MS. likewiſe contained the treatiſes of muſic by Ariſtides Quintilianus, and Bryennius, ſince publiſhed by Meibomius and Dr. Wallis. The Florentine edition of theſe hymns entirely agrees with that printed at Oxford. In 1602, Hercules Bottrigari mentioned the ſame hymns in his harmonical diſcourſe, called "Melone," printed at Ferrara, in 4to. But he derived his knowledge of theſe pieces only from the Dialogues of Galilei; however, he inſerted, in the beginning of his book, ſome fragments of them in common notes; but they were diſfigured by a number of typographical errors.

At length, in the year 1720, M. Burette publiſhed theſe three hymns in the "Memoirs of the Academy des Inſcriptions," tome v. from a copy found at the end of a Greek manuſcript in the king of France's library at Paris, No. 3221, which likewiſe contained the muſical treatiſes of Ariſtides Quintilianus, and of Bacchius ſenior. But though the words were confuſed, and confounded one with another, they appeared much more complete in this manuſcript than elſewhere, particularly the hymn to Apollo, which had ſix verſes more at the beginning; and that to Nemeſis, which, though deficient at the end in all the other editions, was here entire, having fourteen verſes, excluſive of the ſix firſt.

We have been the more ſolicitous to trace the manner in which theſe curious fragments were diſcovered, in order to afford our readers all poſſible ſatisfaction with regard to their authenticity; indeed they have been ſifted, collated, and corrected by the moſt able critics in the Greek language, as well as the moſt ſkilful muſicians of the two laſt centuries. M. Burette has publiſhed the muſic to theſe hymns, in the Memoirs of the Academy des Inſcriptions, tome v. and Dr. Burney, in the firſt volume of his "General Hiſtory of Muſic," has had this muſic engraved both in ancient and modern notation.

Dionysius *Halicarnaſſenſis*, junior, flouriſhed, according to Suidas, under the emperor Adrian, and wrote twenty-ſix books of the "Hiſtory of Muſicians," in which he celebrated not only the great performers on the flute and cithara, but thoſe who had riſen to eminence by every ſpecies of poetry. He was, likewiſe, author of five books, written in defence of muſic, and chiefly in refutation of what is alleged againſt it in Plato's Republic. Ariſtides Quintilianus has alſo endeavoured to ſoften the ſeverity of ſome animadverſions againſt muſic in the writings of Cicero; but though time has ſpared the defence of this author, yet it does not indemnify us for the loſs of that which Dionyſius junior left behind him; as teſtimonies are ſtill remaining of his having been a much more able writer than Ariſt. Quintilianus.

The loſs of the entire works of this writer is ſeverely felt by all muſical hiſtorians, but particularly by thoſe who ſeek information concerning the muſic and muſicians of the ancient Greeks.

Dionysius, *Ear of*, in *Geography*, a large cavern in the iſland of Sicily, cut horizontally into a rock, 72 feet high, 27 broad, and 219 in depth; the entrance of which reſembles the ſhape of an ear, and the inſide ſomewhat the form of the letter S. On the top of the cave there is a groove, which runs from one end to the other, and has communication with a ſmall room at the entrance, now inacceſſible, by reaſon of the height and ſteepneſs of the rock. This is imagined to have been a guard-room, where the tyrant placed a centinel, who, by hearing every the leaſt whiſper of the priſoners within, made his report accordingly to his maſter. Mr. Brydone, in his Travels, gives to the cave the exact form of the human ear, but aſſigns to it larger dimenſions than thoſe above ſtated from Sandwich's "Voyage round the Mediterranean." Some, among later travellers, deny the exiſtence of any other than a rude or fancied reſemblance in the cave to the ſtructure of the ear, and deride the idea of ſuch a deſign in its original formation. Lord Sandwich ſuppoſes this cavern to be the "Latumiæ Syracuſanæ" mentioned by Cicero; but moſt other travellers agree, that the immenſe cavern, which has been converted into a ſubterraneous garden, and belongs to the convent of the capuchins, was the "Latumiæ" to which Cicero alluded.

DIONYSOPOLIS, in *Ancient Geography*, a town of the Hither India, according to Ptolemy, who adds, that it was alſo called *Nagara*. Arrian places it between the Indus and the Cophenes. It was the *Nyſa* of Alexander, and the modern *Nughz*, or *Nagaz*.—Alſo, a town of Lower Mœſia, in the vicinity of the Euxine ſea. Pliny ſays, that it was alſo called *Crunos*; but Pomponius Mela ſays, that Crunos was the name of the port of Dionyſopolis. It is ſaid to have had this name from a ſtatue of Bacchus, which was carried by ſea to this place.—Alſo, an epiſcopal town of Aſia, in the ſecond Pacatian Phrygia; founded by Eumenes and Attalus, who found in this place a ſtatue of Bacchus. Steph. Byz.

DIOPA, or DIONE, a town of the Peloponneſus, in Arcadia.

DIOPHANTINE PROBLEMS, ſo called from the inventor, Diophantus, a ſpecies of indeterminate problems relating to ſquare and cube numbers, and often admitting a variety of anſwers. The ſolution of them depends,

1. On aſſuming ſuitable poſitions to denote the number ſought.

2. On making the propoſed expreſſion a ſquare.

3. Or, on making two propoſed expreſſions ſquares, &c. called the reſolving of a duplicate equality.

Theſe problems ſeldom involve equations of a high order; nevertheleſs, it is extremely difficult to give any general rules by which their ſolution can, with certainty, and in all caſes, be effected.

Yet it will be found, that there are two or three very general principles, on a due application of which the ſolution of almoſt all of them, in great meaſure, depends: theſe are,

1. To reſolve a *ſingle equality*, or to make an expreſſion a ſquare, which is fully illuſtrated in Prob. I. and Art. 30.

2. To find the ſides of whatever right-angled triangles may be required: this is founded on Euc. 47. 1, and is fully illuſtrated in Prob. VII. and the following ones, and forms a tranſition to the

3d Principle. To reſolve a duplicate equality, or to make two given expreſſions ſquares, ſee Prob. XI. &c. and Art. 30, and Edingb. Tranſ. vol. ii. p. 194. This is of very extenſive application, and is the foundation of the

4th Principle. To reſolve two given ſquares into as many other pairs of ſquares as may be required, ſee Prob. XX. and Art. 30. It may be diſtinguiſhed by the name of the variation principle, and may be ſolved, likewiſe, as follows:

Let a^2 and b^2 be the given ſquares, and x^2 and y^2 the required ones. Then $a^2 + b^2 = x^2 + y^2$, or $x^2 = -a^2 - b^2 + y^2$, or $\overline{x+a} \times \overline{x-a} = \overline{b+y} \times \overline{b-y}$, or $\overline{x+a} \times \overline{mx-ma} = \overline{b+y} \times \overline{mb-my}$. Now, if $x + a = mb - my$, then $\overline{mx - ma} = b + y$, or $x - a = \frac{b+y}{m}$, and $x = \frac{b+y+ma}{m}$; whence $\frac{b+y+ma}{m} = mb - my - a$, or $b + y + ma = m^2 b - m^2 y - ma$, or $m^2 y + y = m^2 b - 2ma - b$, and $y = \frac{m^2 b - 2ma - b}{m^2 + 1}$, and $x = \frac{m^2 a + 2mb - a}{m^2 + 1}$.

Cor. 1. If $b = 0$, or one ſquare a^2 be to be divided into two others, we have $x = \frac{m^2 a - a}{m^2 + 1}$, and $y = \frac{-2ma}{m^2 + 1}$, or $\frac{2ma}{m^2 + 1}$, which is Prob. VIII.

PROBLEM I.

To make a Propoſed Expreſſion a Square.

Rule.—Aſſume a ſuitable ſide for it, and make its ſecond power equal to the propoſed expreſſion.

Examples.

1. Required ſuch a value of n, that $n^2 + 1$ may be a ſquare.

Aſſume $n^2 + 1 = \overline{nz - 1}^2 = n^2 + 2nz + z^2$ = a ſquare; then $2nz = z^2 - 1$, and $n = \frac{z^2 - 1}{2z}$, and z may be any number greater than 1.

If $z = 2$; $n = \frac{3}{4}$, and $n^2 + 1 = \frac{9}{16} + \frac{16}{16} = \frac{25}{16}$ = a ſquare.

If $z = 3$, $n = \frac{8}{6}$, and $n^2 + 1 = \frac{64}{36} + \frac{36}{36} = \frac{100}{36}$ = a ſquare, &c. &c. Hence we may find as many right-angled triangles as we pleaſe, all having 1 for their baſe.

2. Required x when $x^2 + x$ is a ſquare.

Aſſume $x^2 + x = \overline{x - z}^2 = x^2 + 2xz + z^2$, then $2xz + x = z^2$, and $x = \frac{z^2}{2z + 1}$.

If $z = 1$, $x = \frac{1}{3}$, and $x^2 + x = \frac{1}{9} + \frac{3}{9} = \frac{4}{9}$ = a ſquare.

If $z = 2$, x is $= \frac{4}{5}$, and $x^2 + x = \frac{16}{25} + \frac{20}{25} = \frac{36}{25}$ = a ſquare, &c.

3. Find an integral value of x, ſuch that $16x^2 + x - 1$ may be a ſquare.

Aſſume $16x^2 + x - 1 = \overline{4x - a}^2 = 16x^2 - 8ax + a^2$, $8ax + x = a^2 + 1$, and $x = \frac{a^2 + 1}{8a + 1} = \frac{2}{9}, \frac{5}{17}$, or $\frac{2}{5}, \frac{17}{33}, \frac{26}{41}, \frac{37}{49}, \frac{50}{57}, \frac{65}{65} = 1$.

Anſ. If $a = 16$, $x = \frac{257}{129}$ almoſt 2.

4. Make $2x^2 - 2x + 1$, a ſquare.

Aſſume $2x^2 - 2x + 1 = \overline{2ax - 1}^2 = 4a^2x^2 - 4ax + 1$, then $2x - 2 = 4a^2 x - 4a$, or $4a^2 x - 2x = 4a - 2$, and $x = \frac{2a - 1}{2a^2 - 1} = 1 \cdot \frac{3}{7}, \frac{5}{17}$, &c.; if $a = \frac{3}{4}$ x is $= 4$, and the given expreſſion $= 25$, &c.

5. Find a value of y, ſuch as may make $3y^2 + 12y + 9$, a ſquare.

Aſſume $3y^2 + 12y + 9 = \overline{3y - 3}^2 = 9y^2 - 18y + 9$, then $3y + 12 = 9y - 18 \cdot 6y = 30$, and $y = 5 \therefore 144$ = ſquare required.

6. Given $\sqrt{7z^2 + 1} = m$, to find m a whole number.

Since $7z^2 + 1 = m^2$, m is leſs than $3z$. Aſſume $7z^2 + 1 = \overline{3z - a}^2 = 9z^2 - 6az + a^2$, $2z^2 - 6az = -a^2 + 1$; $z^2 - 3az = \frac{-a^2 + 1}{z}$; $z^2 - 3az + \frac{9a^2}{4} = \frac{7a^2 + 2}{4}$, and $z = \frac{3a + \sqrt{7a^2 + 2}}{2}$. If $a = 1$, $z = 3$, and $m = 8$.

7. Required a rational value of $\sqrt{v^4 - 2}$.

Aſſume $v^4 - 2 = \overline{v^2 - a^2}^2 = v^4 - 2a^2 v^2 + a^4$, $2a^2 v^2 = a^4 + 2$; $v^2 = \frac{a^4 + 2}{2a^2} = \frac{2a^4 + 4}{4a^2}$. Here $2a^4 + 4$ muſt

be made a ſquare, ſuppoſe $\overline{2 + a^2 b^2}|^2 = 4 + 4 a^2 b^2 + a^4 b^4$, or $2 a^2 = 4 b^2 + a^2 b^4$, $2 a^2 - a^2 b^4 = 4 b^2$, and $a^2 = \frac{4 b^2}{2 - b^4}$ = a ſquare. If $b = 1$, then $a = 2$, $v = \frac{3}{2}$, $v^4 - 2 = \frac{81}{16} - \frac{32}{16} = \frac{49}{16}$, and $\sqrt{v^4 - 2} = \frac{7}{4}$.

8. Find ſuch a value of v as may make $\sqrt{2 - v^4}$ rational, v is leſs than 1.

Aſſume $v = 1 - a$, or $v^4 = 1 - 4a + 6a^2 - 4a^3 + a^4$, then $2 - v^4 = 1 + 4a - 6a^2 + 4a^3 - a^4$ = ſuppoſe $\overline{1 + 2a - 5a^2}|^2 = 1 + 4a - 6a^2 - 20a^3 + 25a^4$; or $25a^4 - 20a^3 = 4a^3 - a^4$; $26a = 24$, and $a = \frac{12}{13}$ $\therefore v = 1 - a = \frac{1}{13}$, and $\sqrt{2 - v^4} = \sqrt{\frac{57122 - 1}{28561}} = \frac{239}{169}$.

9. Make $2x^3 + 2x + 4$ a rational ſquare, when x is not $= \frac{1}{8}$.

Aſſume $2x^3 + 2x + 4 = \overline{2 + 2ax}|^2 = 4 + 8ax + 4a^2x^2$, $x^2 + 1 = 4a + 2a^2x$; $x^2 - 2a^2x = 4a - 1$; $x^2 - 2a^2x + a^4 = a^4 + 4a - 1$, and $x = a^2 + \sqrt{a^4 + 4a - 1}$. To make $a^4 + 4a - 1$ a ſquare, let $b = 4a - 1$, or $a = \frac{b + 1}{4}$, then $a^4 = \frac{b^4 + 4b^3 + 6b^2 + 4b + 1}{256}$, or $a^4 + 4a - 1 = \frac{b^4 + 4b^3 + 6b^2 + 260b + 1}{256}$ to be made a ſquare, ſuppoſe it $= \frac{\overline{1 + 130b - b^2}|^2}{16} = \frac{b^4 - 260b^3 + 16898b^2 + 260b + 1}{256}$, then $4b^3 + 6b^2 = 16898b^2 - 260b^3$, or $2b + 3 = 8449 - 130b$; $132b = 8446$, and $b = \frac{4223}{66}$ $\therefore a = \frac{b + 1}{4} = \frac{4289}{264}$, $x = 528$, and $2x^3 + 2x + 4 = 294396964 = \overline{17158}|^2$.

10. Find ſuch values of x and y, that $x^2 + ay^2 = b^2$ may be rational.

Aſſume $x = b - my$, or $x^2 = b^2 - 2bmy + m^2y^2$, then $b^2 - 2bmy + m^2y^2 + ay^2 = b^2$, or $m^2y^2 + ay^2 = 2bmy$, $m^2y + ay = 2bm$, and $y = \frac{2bm}{m^2 + a}$. But $x^2 = b^2 - ay^2$ $= b^2 - \frac{4b^2am^2}{\overline{a + m^2}|^2} = \frac{b^2 \times \overline{a + m^2}|^2 - 4am^2}{\overline{a + m^2}|^2} = \frac{b^2 \times a^2 - 2am^2 + m^4}{\overline{a + m^2}|^2}$, and $x = \pm \frac{b \cdot \overline{a - m^2}}{a + m^2} = b - my$ $= b - \frac{2bm^2}{a + m^2} = \frac{b \cdot a + m^2 - 2m^2}{a + m^2} = \frac{b \cdot \overline{a - m^2}}{a + m^2}$.

11. Make $1 + 2x - x^2 + x^3$ a ſquare.

Aſſume $\overline{1 + x}|^2 = 1 + 2x + x^2 = 1 + 2x - x^2 + x^3$, or $x^2 = x^3 - x^2$, $2x^2 = x^3$ and $x = 2$.

12. Make $4 + 6x - 5x^2 + 3x^3$ a ſquare.

Aſſume it $= \overline{2 + ax}|^2 = 4 + 4ax + a^2x^2$. Now to make the ſecond term vaniſh from each ſide, as well as the 1ſt, $4a$ muſt be $= 6$, or $a = \frac{3}{2}$. Then $\frac{9x^2}{4} = 3x^3 - 5x^2$, or, $\frac{29x^2}{4} = 3x^3$, and $x = \frac{29}{12}$, and the expreſſion $= \sqrt{\frac{8}{2} + \frac{29}{2} + \frac{29}{64}}^2 = \frac{45}{8} = 5\frac{5}{8} = \sqrt{\frac{18235}{576}} = \sqrt{\frac{2025}{64}}$.

13. Make $a^2 + bx + cx^2 + dx^3 + ex^4$ a ſquare. Aſſume it $= \overline{a + mx + nx^2}|^2 = a^2 + 2amx + \left.\begin{matrix}2an \\ m^2\end{matrix}\right\} x^2 + 2mnx^3 + n^2x^4$. Here $2am = b$, or $m = \frac{b}{2a}$, and $2an + m^2 = c$, or $n = \frac{c - m^2}{2a}$, then $dx^3 + ex^4 = 2mnx^3 + n^2x^4$: $d + ex = 2mn + n^2x$; $ex - n^2x = 2mn - d$, and $x = \frac{2mn - d}{e - n^2}$.

14. Make $a + ex^4$ a ſquare. Suppoſe one value of $x = n$, and $a + en^4 = s^2$. To find other values of x, put $x = n + y$, or $x^4 = n^4 + 4n^3y + 6n^2y^2 + 4ny^3 + y^4$, then $a + ex^4 = a + en^4 + 4en^3y + 6en^2y^2 + 4eny^3 + ey^4$, or writing s^2 for $a + en^4$, $s^2 = 4en^3y + 6en^2y^2 + 4eny^3 + ey^4$ is to be made a ſquare, as the 13th.

Prob. II.

15. To find two numbers, x and y, ſuch that $x^2 + y$ may be a ſquare, and $x + y$ its root. We have $x^2 + y = \overline{x + y}|^2 = x^2 + 2xy + y^2$, $y = 2xy + y^2$, $y + 2x = 1$, and $y = 1 - 2x$, where x may be any fraction leſs than $\frac{1}{2}$. Suppoſe $x = \frac{1}{3}$, then $y = \frac{1}{3}$, $x^2 + y = \frac{4}{9}$, and $x + y = \frac{2}{3}$ its root, if $x = \frac{2}{5}$, $y = \frac{1}{5}$, $x^2 + y = \frac{9}{25}$, and $x + y = \frac{3}{5}$, &c. &c.

Prob. III.

16. To find two numbers, x and y, ſuch that $x + y$ may be a ſquare, and $x^2 + y$ its root.

Let $x^2 + y = nx$, then $x + y = n^2x^2$, whence $y = n^2x^2 - x = nx - x^2$, $n^2x + x = n + 1$, and $x = \frac{n + 1}{n^2 + 1}$, $y = \overline{n - x} \cdot x$, ſuppoſe $n = 2$, $x = \frac{3}{5}$, $y = \frac{21}{25}$, and $x + y = \frac{36}{25}$, and $x^2 + y = \frac{36}{25} = \frac{6}{5}$.

Prob. IV.

17. To find a number which being divided into any two parts, x and y, $x^2 + y$ may be always equal to $y^2 + x$.

1. Let az and bz denote the required parts, then $a^2z^2 + bz = az + b^2z^2$; $a^2z + b = a + b^2z$, or $a^2z - b^2z = a - b$, and $z = \frac{a - b}{a^2 - b^2} = \frac{1}{a + b}$, and $az = \frac{a}{a + b}$ = one part, and $bz = \frac{b}{a + b}$ = the other part, and both added together = $\frac{a + b}{a + b} = 1$, the number required.

For let x and $1 - x$ be any two parts of 1. Then $x^2 + 1 - x = \overline{1 - x}|^2 + x = 1 - 2x + x^2$, or, 2d if $x^2 + y + x = y^2 + x$, or $x^2 - y^2 = x - y$, then $x + y = 1$.

To find two numbers, ſuch that their ſum being increaſed and leſſened either by their difference, or the difference of their ſquares, the ſums and remainders ſhall be all ſquares.

18. Let $25x^2$ be the ſum, and $24x^2$ the difference of the required numbers. Then $25x^2 \pm 24x^2$ are evidently ſquares.

More-

Moreover, $\frac{25x^2}{2} + \frac{24x^2}{2} = \frac{49x^2}{2}$ = greater number, and $\frac{x^2}{2}$ = leſs; the diff. of their ſquares is $\frac{2400x^4}{4} = 600x^4$.

The two remaining conditions are, that $25x^2 \pm 600x^4$ are to be ſquares. Divide by $25x^2$, then $1 \pm 24x^2$ are to be ſquares; firſt make $1 - 24x^2$ a ſquare: Aſſume $\overline{1 - ax}|^2 = 1 - 2ax + a^2x^2 = 1 - 24x^2$, or, $a^2x^2 + 24x^2 = 2ax$; $a^2x + 24x = 2a$, and $x = \frac{2a}{a^2 + 24}$ (if $a = 4$) $\frac{8}{40} = \frac{1}{5}$, and $x^2 = \frac{1}{25}$. Therefore, $\frac{49}{50}$, and $\frac{1}{50}$, are the numbers required.

Prob. V.

19. To find two ſquare numbers ſuch, that the ſum of them may be a ſquare, the difference of them a cube, and the roots of the ſquare and cube equal.

Since the ſum of the two numbers is to be a ſquare, let $9x^2$ and $16x^2$ denote the numbers ſought, then their ſum $25x^2$ is a ſquare, but their diff. $7x^2$ is to be a cube, and $5x = \overline{7x^2}|^{\frac{1}{3}}$ per the laſt condition of the queſtion. We have $125x^3 = 7x^2$, or $x = \frac{7}{125}$, $9x^2 = \frac{441}{15625}$, and $16x^2 = \frac{784}{15625}$ = the numbers required.

Prob. VI.

20. To find three numbers A, B, and C, ſuch that $A^2 + BC$, $B^2 + AC$, and $C^2 + AB$, may be all ſquares.

Let 1, $x-1$, and $4x$, denote the three numbers required; then the two firſt conditions are ſatisfied; for $A^2 + BC = 1 + 4x^2 + 4x = \overline{2x - 1}|^2$, and $B^2 + AC = \overline{x-1}|^2 + 4x = x^2 + 2x + 1 + 4x = \overline{x + 1}|^2$; ſo that we have only to make $C^2 + AB = 16x^2 + x - 1$ a ſquare.

Aſſume $\overline{4x - a}|^2 = 16x^2 - 8ax + a^2 = 16x^2 + x - 1$, or $8ax + x = a^2 + 1$, or $x = \frac{a^2 + 1}{8a + 1}$; and the three numbers are 1, $\frac{a^2 - 1}{8a + 1} - 1$, and $\frac{4 \cdot \overline{a^2 + 1}}{8a + 1}$; or in a common denominator $\frac{8a + 1}{8a + 1}$, $\frac{a^2 - 8a}{8a + 1}$, and $\frac{4 \cdot \overline{a^2 + 1}}{8a + 1}$. Or, $8a + 1$, $a^2 - 8a$, and $4 \cdot \overline{a^2 + 1}$, where a may be any number greater than 8. If $a = 9$, the numbers are 73, 9, and 328. If $a = 10$, the numbers are 81, 20, 404, &c. &c.

Prob. VII.

21. To find two ſquare integers, whoſe ſum may be a $\square$; or to find as many right-angled triangles, in whole numbers, as we pleaſe.

Take r and s, any two unequal numbers, r the greater; then make $\overline{r^2 - s^2}|^2 = r^4 - 2r^2s^2 + s^4$, and $\overline{2rs}|^2 = 4r^2s^2$, the ſquare number required. For their ſum is $r^4 + 2r^2s^2 + s^4 = \overline{r^2 + s^2}|^2$ = a ſquare.

Prob. VIII.

22. To divide a given ſquare C^2 into two other ſquares a^2 and b^2: or from a given hypothenuſe, to find the ſides of a right-angled triangle.

1. We have $C^2 - a^2 = b^2 = \square$, which put $= \overline{na - c}|^2 = n^2a^2 - 2nac + c^2$; then $c^2 = a^2 + b^2 = a^2 + n^2a^2 - 2nac + c^2$, or $2nac = n^2a^2 + a^2$; $2nc = n^2a + a = a \cdot \overline{n^2 + 1}$, and $a = \frac{2nc}{n^2 + 1}$; therefore, if a and n be rational, b will be ſo.

Ex. If $c = 5$, $n = 1$, then $a = 5$, and $b = 0$. If $c = 2$, $n = 3$, then $a = \frac{6}{5}$,

$n = 2$ $\quad a = 4$ $\quad b = 3$,
$n = 3$ $\quad a = 3$ $\quad b = 4$,
$n = 4$ $\quad a = \frac{40}{17}$ $\quad b = \frac{75}{17}$.

Or, thus:

2. Let C^2 = the given ſquare, a^2 one of its parts, and $c^2 - a^2$, the other to be made a ſquare. Aſſume it $= \overline{ra - c}|^2 = a^2r^2 - 2arc + c^2$; or, $2arc = r^2a^2 + a^2$, $2rc = r^2a + a$, and $a = \frac{2rc}{r + 1}$, as above.

Or, thus: 3. Let $\overline{sa}|^2 = s^2a^2$, and $\overline{ra - c}|^2 = r^2a^2 - 2arc + c^2$ be the two ſquares into which c^2 is to be reſolved. Then $c^2 - s^2a^2 = r^2a^2 - 2arc + c^2$; $2arc = r^2a^2 + s^2a^2$; $2rc = r^2a + s^2a$, and $a = \frac{2rc}{r^2 + s^2}$. $\therefore sa = \frac{2rsc}{r^2 + s^2}$ = the root of one of the ſquares ſought, and $ra - c = \frac{2r^2c}{r^2 + s^2} - \frac{c}{1} = \frac{2r^2c - r^2c - s^2c}{r^2 + s^2} = \frac{r^2c - s^2c}{r^2 + s^2}$ = root of the other.

1. Hence c, $\frac{2rsc}{r^2 + s^2}$, and $\frac{r^2c + s^2c}{r^2 + s^2}$ are the roots of three ſquares, of which the ſum of the two laſt ſquares is equal to the firſt, or the three roots are the ſides of a right-angled triangle, whoſe hypothenuſe is equal c.

2. If each of theſe ſides be multiplied by $r^2 + s^2$, we ſhall have $r^2c + s^2c$, $2rsc$, and $r^2c - s^2c$ for the three ſides of another triangle; or, by dividing each by c, we have $r^2 + s^2$, $2rs$, and $r^2 - s^2$.

Prob. IX.

23. To find two numbers whoſe ſum and difference may be both ſquares. If $r^2 + s^2$ be one of the numbers, and $2rs$ the other, the problem is ſolved. But $r^2 + s^2$ is equal the ſquare of the hypothenuſe of a right-angled triangle, and $2rs$ the double product of its ſides; therefore, the ſquare of the hypothenuſe $\pm$, the double product of its ſides, is always a ſquare.

Prob. X.

24. Given the difference of two ſquares to find the ſquares.

Rule.—Reſolve the given difference into any two factors, and the $\frac{1}{2}$ ſum of them is the root of the greater ſquare, and the $\frac{1}{2}$ difference the root of the leſſer. For $c^2 - a^2 = \overline{c + a} \cdot \overline{c - a}$.

Ex.—Find two ſquares whoſe difference may be 12. Factors 2 and 6, $\frac{1}{2}$ ſum 4, $\frac{1}{2}$ diff. 2. Or, factors 3 and 4, $\frac{1}{2}$ ſum $\frac{7}{2}$, $\frac{1}{2}$ diff. $\frac{1}{2}$, and $\frac{49}{4} - \frac{1}{4} = 12$.

Prob XI.

25. To reſolve a duplicate equality, or to make two propoſed expreſſions ſquares.

General Rule.

Reſolve the difference of the propoſed ſquares into two ſuch factors, that the ſquare of the $\frac{1}{2}$ ſum of them may be made

made equal to the greater ſquare, or the ſquare of their $\frac{1}{2}$ difference to the leſs.

Ob.—This problem differs from the laſt in having the propoſed ſquares limited in form or magnitude.

Examples.

Of the reſolution of a duplicate equality.

1. Find ſuch a value of x, that $x + 1$, and $x - 1$, may both be ſquares. The difference is 2. Factors 1 and 2, $\frac{1}{2}$ ſum $\frac{3}{2}$, $\frac{1}{2}$ diff. $\frac{1}{2}$ and $\frac{9}{4}$, $\frac{1}{4}$ the two ſquares, therefore $x = \frac{5}{4}$.

2. Find x when $x^2 + x$, and $x^2 - x$, are ſquares, their ſum is $2x^2$, we are to find two ſquares whoſe ſum is $2x^2$. But $\frac{x}{25} + \frac{49x^2}{25} = \frac{50x^2}{25}$. Put $x^2 - x = \frac{x^2}{25}$, or $x - 1 = \frac{x}{25}$, $24x = 25$, and $x = \frac{25}{24}$.

Or let c^2 = hypothenuſe, and p = double product of ſides, then $c^2 + p$ and $c^2 - p$ are ſquares (per 23.), conſequently $c^2 z^2 + p z^2$, and $c^2 z^2 - p z^2$ are ſquares. We have only to find ſuch a value of z, that $c^2 z^2$ may be = the ſquare of $p z^2$. Let $c z = p z^2$, and $z = \frac{c}{p}$; $z^2 = \frac{c^2}{p^2}$, and $p z^2 = \frac{c^2}{p} = x$ = the number required, *i. e.* the ſquare of any hypothenuſe divided by the double product of the ſides gives x.

As 3, 4, 5, gives $\frac{25}{24} = x$, 5, 12, 13, gives $\frac{169}{120}$, &c.

3. Make $2x^2 + 1$, and $4x + 1$, ſquares, while x has the ſame value in both. The difference is $2x^2 - 4x$, the factors $2x$ and $x - 2$, the difference $\frac{x}{2} + 1$. Put the leſs ſquare $4x + 1 = \overline{\frac{x}{2} + 1}^2 = \frac{x^2}{4} + x + 1$, or $16x = x^2 + 4x$, or $x = 12$, and the propoſed expreſſions are $289 = \overline{17}^2$ and 49.

4. Find ſuch a value of x, as may make $10 - 2x$, and $10 - x^2$ ſquares. Diff. $x^2 - 2x$. Factors x and $x - 2$. The $\frac{1}{2}$ diff. = 1 = leſs ſquare = $10 - x^2$, or $x = 3$. Or, $\frac{1}{2}$ ſum = $x - 1$, and $x^2 - 2x + 1 = 10 - 2x$, $x^2 = 9$, and $x = 3$.

5. To make $ax + c$, and $bx + d$ both ſquares, where a is greater than b, and the ſigns either + or −.

Rule. Let $q = \frac{b}{a - b}$. Mult. the diff. of the given ſquares by q, and ſubtract the prod. from the leſs ſquare. Call the remainder r. Then if r, or $\frac{-q}{r}$, be a ſquare, the duplicate equality is reſolvable: thus, find two ſquares m^2 and n^2, the diff. of which may be to the exceſs of the leſs above r as 1 : 9. When r is a ſquare, $\overline{y + \sqrt{r}}^2$ muſt be made equal to $n^2 = bx + d$, but when $\frac{-q}{r}$ is a ſquare, n^2 muſt be made equal to $bx + d$.

Ex.—Make $8x + 4$, and $6x + 4$ both ſquares; their difference is $2x$ and $q = 3$, product $6x$, and $r = 4$ a ſquare. Here $\overline{y + 2}^2 = n^2 = y^2 + 4y + 4$, or $n^2 - 4 = y^2 + 4y$ $\therefore m^2 - n^2 = \frac{y^2 + 4y}{3}$, and $m^2 = y^2 + 4y + 4 + \frac{y^2 + 4y}{3} = \frac{4y^2}{3} + \frac{16y}{3} + 4$; to avoid fractions multiply by 9, then $9m^2 = 12y^2 + 48y + 36$ or $\frac{9m^2}{4} = 3y^2 + 12y + 9$ to be made a ſquare: $y = 5$ $\therefore n^2 = 49 = 6x + 4$, and $x = \frac{45}{6}$ $\therefore 8x + 4 = 64$.

PROB. XII.

26. To find two numbers, A and B, ſuch that A + B, $A^2 + B$, and $B^2 + A$, may be all ſquares. Let $x = A$, $3x^2 = B$,

Then $A^2 + B = 4x^2$ is a ſquare.

But $A^2 + B = 3x^2 + x$,

And $B + A = 9x^4 + x$ are to be ſquares.

The difference is $9x^4 - 3x^2$. Factors $3x^2$ and $3x^2 - 1$, &c. $x = \frac{1}{6}$, $A = 3x^2 = \frac{1}{12} = B$.

PROB. XIII.

27. To find two numbers, A and B, ſuch that, A + 1, B + 1, A + B + 1, and A − B + 1, may be all ſquares.

1. Let $A = x^2 + 2x$, and $B = x^2 - 2x$, and the two firſt conditions are ſatisfied; but $2x^2 + 1$, and $4x + 1$, are alſo to be ſquares; (per XI. 3.) $x = 12$, $A = 168$, $B = 120$.

2. Let $A = 9x^2 + 6x$, $B = y^2 - 1$, then $A + B + 1 = 9x^2 + 6x + y^2$ = a ſquare is the third condition, ſuppoſe it $= z^2$; then $z^2 - y^2 = 9x^2 + 6x$. Factors x and $9x + 6$, $\frac{1}{2}$ diff. $= 4x + 3$; or $y^2 = 16x^2 + 24x + 9$; or $B = 16x^2 + 24x + 8$. But $B - A + 1 = 7x^2 + 18x + 9$ is alſo to be a ſquare, ſuppoſe $= \overline{3x - 3}^2 = 9x^2 - 18x + 9$; or $2x^2 = 36x$, and $x = 18$ $\therefore A = 3024$, $B = 5624$; $B + A = 8648$, $B - A = 2600$, each of which + 1 is the ſquare of 55, 75, 93, and 51.

PROB. XIV.

28. To find three numbers ſuch, that if the ſquare of each be added to the ſum of the two, the three ſums may be ſquares.

1ſt. $\overline{x + 1}^2 = x^2 + 2x + 1$ $\therefore$ if x, $2x$, and 1, denote the three numbers, the firſt condition is ſatisfied. But $4x^2 + x + 1$, and $3x + 1$, are alſo to be made ſquares.

Difference is $4x^2 - 2x$. Factors x, and $4x - 2$, $\frac{1}{2}$ diff. $\frac{3x}{2} - 1$ $\therefore \frac{9x^2}{4} - 3x + 1 = 3x + 1$. $9x^2 = 24x$, $x = \frac{8}{3}$ $2x = \frac{16}{3}$, and 1, are the numbers required.

PROB. XV.

29. To find two numbers, A and B, ſuch that A B + A, A B + B, and A B + A + B, may be all ſquares.

Let $x = A$, $x^2 = A B + A$ = a ſquare; then $x^2 - x = A B$, and $x - 1 = B$, and $2x - 1 = A + B$. But $A B + B = x^2 - 1$, and $A B + A + B = x^2 + x - 1$, are to be made ſquares. Diff. is x. Factors $2x$ and $\frac{1}{2}$, $\frac{1}{2}$ diff. $x - \frac{1}{4}$, or $x^2 - \frac{x}{2} + \frac{1}{16} = x^2 - 1$, or $\frac{x}{2} = 1 + \frac{1}{16} = \frac{17}{16}$, and $x = \frac{17}{8} = A$, and $B = x - 1 = \frac{9}{8}$.

Scholium. 30. To find the proper factors, into which the difference of any propoſed ſquare ought to be reduced.

Rule. Put z = one of the factors, and the given difference divided by z = the other; then by making the ſquare of the $\frac{1}{2}$ ſum or $\frac{1}{2}$ difference equal to the greater or leſs of the propoſed ſquares, find ſome ſuitable value of z.

Examples.

1. Find the proper factors of the diff. x, when $x^2 + x - 1$ and $x^2 - 1$ are to be ſquares.

Let z and $\frac{x}{z}$ = the factors; the $\frac{1}{2}$ diff. = $\frac{x}{2z} - \frac{z}{2}$, or $\frac{x^2}{4z^2} - \frac{x}{2} + \frac{z^2}{4} = x^2 - 1$. We ſee that x may have a rational value, if $\frac{x^2}{4z^2} = x^2$, or $4z^2 = 1$, and $z = \frac{1}{2}$ $\therefore$ $\frac{x}{z} = 2x$ the factors.

2. Find the proper factors for making two ſquares, m^2 and n^2, whoſe difference is d, ſuch that the leaſt, n^2, may exceed any given number c.

Factors z and $\frac{d}{z}$; $\frac{1}{2}$ difference $= \frac{z}{2} - \frac{d}{2z}$, or $\frac{\overline{z^2 - d}^2}{2z} = \frac{z^4 - 2dz^2 + d^2}{4z^2} = n^2$, is to be greater than c, or $z^4 - 2dz^2 + d^2$ greater than $4z^2c$, or $z^2 - 4z^2c - 2dz^2 + d^2$ greater than 0.

Let $z^4 - 4z^2c - 2dz^2$ greater than 0, or $z^2 - 4c - 2d$ greater than 0; and $z^2 =$, or greater than $4c + 2d$.

Cor. If $c = nd$, then $z^2 =$, or greater than $d \cdot \overline{4n + 2}$. Hence, if we take $d =$ a ſquare, as many right-angled triangles as we pleaſe may be found, all having the ſame baſe $= \sqrt{d}$.

PROB. XVI.

31. To find two numbers ſuch, that the ſquare of each, being added to the ſum of both, may make two ſquare numbers.

1. Let $x =$ one of the numbers; its ſquare is x^2, and $x^2 + 2x + 1$ is a ſquare. Let $2x + 1$ be the ſum of both numbers; then $x + 1 =$ the greater, its ſquare is $x^2 + 2x + 1$, and if we add the ſum of both, $x^2 + 4x + 2$ is to be made a ſquare, ſuppoſe $= \overline{x - z}^2 = x^2 - 2xz + z^2$, or, $2xz + 4x = z^2 - z$, and $x = \frac{z^2 - 2}{2z + 4}$, where z may be any number greater than $1\frac{1}{2}$, if $z = 2$, $x = \frac{1}{4}$, and $x + 1 = \frac{5}{4}$, &c.

PROB. XVII.

32. To find two ſuch numbers, that their product $\pm$ their ſum may be ſquares.

1. Let $x =$ one of the numbers, and $a^2x + b^2x =$ the other: the $a^2x^2 + b^2x^2 =$ their product: but $a^2x^2 \pm 2abx^2 + b^2x^2 = \overline{ax \pm bx}^2 =$ a ſquare. We have only to make $2abx^2 = a^2x + b^2x + x =$ the ſum of the two numbers: or, $x = \frac{a^2 + b^2 + 1}{2ab}$, where a and b may be any numbers at pleaſure: if $a = 1$, $b = 2$, then $x = \frac{3}{2}$, and $\frac{15}{2} =$ greater: for their product $= \frac{45}{4}$, and ſum $= \frac{36}{4}$; and $\frac{81}{4}$, or $\frac{9}{4}$, are ſquares.

PROB. XVIII.

33. To find three numbers ſuch, that their ſum and the ſum of every two of them may be ſquares.

1. Let $x^2 + 2x + 1 = \overline{x + 1}^2$ be the ſum of the three: Let x^2 be the ſum of the firſt and ſecond: then $2x + 1 =$ third number: Let $x^2 - 2x + 1$ be the ſum of the ſecond and third numbers: then $x^2 - 4x$ is the ſecond number, which taken from x^2 leaves $4x$ for the firſt number $\therefore$ the three numbers required are $4x$, $x^2 - 4x$, and $2x + 1$.

2. But the ſum of the firſt and third $= 6x + 1$ is alſo to be a ſquare, ſuppoſe $= a^2$: then $x = \frac{a^2 - 1}{6}$: where a^2 may be any ſquare number greater than 25; becauſe the ſecond number $= x^2 - 4x$, or $x - 4$ muſt be greater than 0 $\therefore$ x greater than 4, bx greater than 24, and $bx + 1$ greater than 25.

Examples.

1. Suppoſe $a^2 = 49$: then $x = 8$, $4x = 32$, $x^2 - 4x = 32$, and $2x + 1 = 17$

$a^2 = 121$ $x = 20$ 80 320 41, &c.

PROB. XIX.

34. To find a number which being divided into any two parts, the ſquare of either part + 100 times the other part, ſhall make a ſquare number.

Let $y =$ the number ſought: x one part, and $y - x =$ the other: then $x^2 + 100y - 100x$ is to be a ſquare, ſuppoſe $\overline{x - z}^2 = x^2 - 2xz + z^2$, or $100y - 100x = z^2 - 2zx$: Now as the object is to find y without limiting x; let $2z = 100$, or $z = 50$: then $100y = 2500$, or $y = 25$: therefore $x^2 + 100 \cdot \overline{25 - x}$ will be a ſquare, let x be what it will.

GENERALLY.

To determine y when $s^2x^2 + z \cdot \overline{y - x}$ is a ſquare.

Let $s^2x^2 + ry - rx = \overline{sx - z}^2 = s^2x^2 - 2szx + z^2$: let $r = 2sz$, then $2szy = z^2$, and $y = \frac{z}{2s}$; but $z = \frac{r}{2s}$ $\therefore$ $y = \frac{r}{4s^2}$, where r may be $=$ any ſquare number, and $s = 1$.

PROB. XX.

35. To find two numbers in the ratio of $a : b$, ſuch that either of them, added to the ſquare of the other, may make a ſquare.

Firſt, let $n - x =$ the leſs of the two numbers ſought, and $4nx =$ greater: then $\overline{n - x}^2 + 4nx = \overline{n + x}^2$ one condition ſatisfied. Second, but $a : b :: n - x : 4nx$: or $4anx = bn - bx$; or $x = \frac{bn}{4an + b}$.

Therefore, $n - x = \frac{4an^2 + bn - bn}{4an + b} = \frac{4an^2}{4an + b} =$ leſs number, and $4nx = \frac{4bn^2}{4an + b} =$ greater. the ſquare of which + the leſs is alſo to be a ſquare.

Or, $\frac{16b^2n^4}{16a^2n^2 + 8abn + b^2} + \frac{4an^2}{4an + b} = \frac{16b^2n^4 + 16a^2n^3 + 4abn^2}{16a^2n^2 + 8abn + b^2}$; or, $4b^2n^4 + 4a^2n^3 + abn^2$ is to be made a ſquare: ſuppoſe $= \overline{2bn^2 - zn}^2$ (z being greater than ab) $= 4b^2n^4 - 4bzn^3 + z^2n^2$, or $4a^2n^3 + 4bzn^3 = z^2n^2 - abn^2$: or $n = \frac{z^2 - ab}{4a^2 + 4bz}$. Third, or to make $16b^2n^4 + 16a^2n^3 + 4abn^2$ a ſquare, ſuppoſe it $= \overline{4bn^2 - zn}^2$ (z^2 being greater than $4ab$). Then $16a^2n^3 + 8bzn^3 = z^2n^2 - 4abn^2$; or $n = \frac{z^2 - 4ab}{16a^2 + 8bz}$.

If $z = 10$, $a = 2$, $b = 3$, then $n = \frac{1}{4}$ and $\frac{2}{20}$ and $\frac{3}{20}$ the numbers required.

Lemma.

Lemma.—36. There are many numbers which cannot be divided into two rational ſquares.

1ſt. Every even ſquare number is diviſible by 4: for its root may be $2x$ and $4x^2$ the number.

2d. Every odd ſquare number -1 is diviſible by 4: for its root is $2x+1$ and $4x^2+4x+1$ the number.

3d. Every number = the ſum of two even ſquares is diviſible by 4. Per 1ſt.

4th. Every number = the ſum of two odd ſquares -2 is diviſible by 4. Per 2d.

5th. Every number = the ſum of an even and an odd ſquare -1 is diviſible by 4. Per 1ſt and 2. Hence,

6th. If any number being divided by 4 leave a remainder equal 3, it cannot be compoſed of two integral ſquares. Nor of two ſquare fractions.

Prob. XXI.

37. To divide any number compoſed of two known ſquares, as a^2+b^2 into two other ſquares.

Let r be greater than s, and not as $a:b$, nor as $a+b:a-b$.

Aſſume $\overline{rx-a}^2 = a^2$, and $\overline{sx-b}^2 = b^2$, or $a^2+b^2 = a^2+b^2+(r^2x^2+s^2x^2-2arx-2bsx)$, or $r^2x+s^2x = 2ar+2bs$, and $x = \frac{2ar+2bs}{r^2+s^2}$ $\therefore rx - a = \frac{2ar^2+2bsx-ar^2-as^2}{r^2+s^2} = \frac{ar^2+2bsx-as^2}{r^2+s^2}$ = ſide of greater ſquare, and $sx-b = \frac{2asx+2bs^2-bx^2-bs^2}{r^2+s^2} = \frac{2ars+bs^2-bx^2}{r^2+s^2}$ = ſide of leſs ſquare.

Let $d = r^2-s^2$, $e = 2rs$, and $f = r^2+s^2$: then

$ar^2-as^2+2brs = ad+be$
$2ars-br^2+bs^2 = ae-bd$
} and $\begin{cases} \frac{ad+be}{f} = \text{ſide of greater ſq.} \\ \frac{ae-bd}{f} = \text{ſide of leſs ſq.} \end{cases}$

Ob. 1. If $b = 0$, this prob. and its ſolution, becomes the ſame as Prob. VIII. *viz.* $\frac{ad}{f}$ and $\frac{ae}{f}$ are the ſides of the required ſquares.

Ob. 2. If $\overline{sx+b}^2$ had been aſſumed $= b^2$, the reſults would have been $\frac{ad-be}{f}$ = ſide of greater, and $\frac{ac+bd}{f}$ = ſide of the leſſer ſquare.

The four fractions exhibiting both ſolutions are, $\frac{ad}{f}$, $\frac{ac}{f}$, $\frac{bd}{f}$, $\frac{be}{f}$. Hence, if d, e, and f be the ſides of a right-angled triangle, and a and b the roots of the original ſquares, and the two ſides of the triangle be multiplied by the roots of the ſaid ſquares, and ſet down in order, thus, $\frac{ad}{f}$, $\frac{ac}{f}$, $\frac{bd}{f}$, $\frac{bc}{f}$: then the ſum of the extremes and difference of the means will be the ſides of the two ſquares required.

Examples.

38. 1. Required to divide $2 = 1^2+1^2$ into two unequal ſquares. 1. Let the triangles be 3, 4, and 5; then the fractions are $\frac{3}{5}$, $\frac{4}{5}$, $\frac{3}{5}$, $\frac{4}{5}$, and $\frac{7}{5}$, and $\frac{1}{5}$, the ſides of $\frac{49}{25}+\frac{1}{25} = 2$.

2. Let the triangle be 8, 6, 10; then the fractions are $\frac{8}{10}$, $\frac{6}{10}$, $\frac{8}{10}$, $\frac{6}{10}$, $\frac{14}{10}$, and $\frac{2}{10}$, as above.

If the triangle be 5, 12, 13, then $\frac{5}{13}$, $\frac{12}{13}$, $\frac{5}{13}$, $\frac{12}{13}$, $\frac{17}{13}$, and $\frac{7}{13}$ are the ſides of $\frac{289}{169}+\frac{49}{169} = \frac{338}{169} = 2$.

3. Let 1 be divided into two ſquares. Here $b = 0$, and $\frac{ad}{f}$ and $\frac{ae}{f}$ are the ſides of the ſquares required.

If the triangle be 3, 4, 5, we have $\frac{4}{5}$ and $\frac{3}{5}$.

If the triangle be 5, 12, 13, we have $\frac{12}{13}$ and $\frac{5}{15}$ the ſides of $\frac{144}{169}$, and $\frac{25}{169} = 1$.

Prob. XXII.

39. To find four right angled triangles, in whole numbers, all having the ſame hypothenuſe.

Solution.—1. Take any two right-angled triangles, not ſimilar, as $\left\{\begin{matrix} a, & b, & c. \\ 3, & 4, & 5, \end{matrix}\right\}$ and $\left\{\begin{matrix} d, & e, & f. \\ 5, & 12, & 13. \end{matrix}\right\}$.

Multiply the three ſides of the firſt by f, and we have af, bf, $cf = 39, 52, 65$. Mult. 2nd by c, we have dc, ec, $cf = 25, 60, 65$, per 37, $ad+be$, $ae \sim bd$, and $cf = 63, 16, 65$; or, $ae+bd$, $ad \sim be$, and $cf = 56, 33, 65$.

Prob. XXIII.

40. To find four numbers, which, being ſeverally added to, or ſubtracted from, the ſquare of their ſum, ſhall make the ſeveral ſums, or remainders, all ſquare numbers.

1. Find (per 39.) four right-angled triangles, having the ſame hypothenuſe, which ſuppoſe $= h$.

Let p, p', p'', p''', denote the double product of their ſides. Then $h^2 \pm p$, $h^2 \pm p'$, $h^2 \pm p''$, $h^2 \pm p'''$, are all ſquares (per 23.); conſequently, $h^2x^2 \pm px^2$, $h^2x^2 \pm p'x^2$, $h^2x^2 \pm p''x^2$, and $h^2x^2 \pm p'''x^2$, are all ſquares.

2. But the condition is, that h^2x^2 ſhall be the ſquare of the ſum of $px^2+p'x^2+p''x^2+p'''x^2$.

Let $p+p'+p''+p''' = e$. Then h^2x^2 is to be = the ſquare of ex^2, or $hx = ex^2$, and $x = \frac{h}{e}$, or $x^2 = \frac{h^2}{e^2}$. Therefore, px^2, $p'x^2$, $p''x^2$, $p'''x^2$, are $= \frac{ph^2}{e^2}$, $\frac{p'h^2}{e^2}$, $\frac{p''h^2}{e^2}$, $\frac{p'''h^2}{e^2}$, which are reſpectively the numbers required.

Demonſtration.—For the ſum of theſe four numbers is $\frac{ph^2+p'h^2+p''h^2+p'''h^2}{e^2} = \frac{eh^2}{e^2} = \frac{h^2}{e}$, and the ſquare of their ſum is $\frac{h^2}{e^2}$. But $\frac{h^4}{e^2} \pm \frac{ph^2}{e^2} = \frac{h^2 \pm ph^2}{e^2} = \frac{h^2}{e^2} \cdot h^2 \pm p$ = a ſquare (per 23,) &c. with the reſt.

Example. The four triangles in 39 give $h^2 = 4225$, $p = 4056$, $p' = 3000$, $p'' = 2016$, $p''' = 3696$, and $e^2 = 27888049$, and the four numbers are $\frac{17136600}{27888049}$, $\frac{12675000}{27888049}$, $\frac{8517600}{27888049}$, and $\frac{15615600}{27888049}$, and their ſum $= \frac{53944800}{27888049}$.

Prob. XXIV.

41. To find three numbers a, b, c, ſuch that, e being any given number, $ab+e$, $ac+e$, and $bc+e$, may be all ſquares.

Firſt.

1. Suppoſe a and b found. Put $ab + e = n^2$, then $ab = n^2 - e$. 2. To find a, b, and n, without trials, take any two numbers, r and s, r the greater, ſo that the ſquare of either may be greater than e, and let $a = n + r$, $b = n - s$, then $ab = n^2 + rn - sn - rs = n^2 - e$ (1), or $n = \frac{rs - e}{r - s}$, $n + r = a = \frac{r^2 - e}{r - s}$, $n - s = b = \frac{s^2 - e}{r - s}$.

3. From $ab + e$, already made a ſquare, take $ae + e$, the difference is $ab - ac = a \cdot \overline{b - c}$ the factors (25.) The $\frac{1}{2}$ ſum is $\frac{a + b - c}{2}$, the $\frac{1}{2}$ difference is $\frac{a - b + c}{2}$. 4. Again, from $ab + e$ take $bc + e$, the diff. is $ab - be = b \cdot \overline{a - c}$, the $\frac{1}{2}$ ſum is $\frac{a + b - c}{2}$, and $\frac{1}{2}$ diff. $\frac{a - b - c}{2}$. Therefore if ſuch a value of c can be found, that $\left|\frac{a + b - c}{2}\right|^2$ may be $= ab + e = n^2$, the problem is ſolved.

Let $\frac{a + b - c}{2} = \pm n$, then $c = a + b \pm 2n$, either of which values of c with a and b above are the numbers required.

5. But $a = n + r$, and $b = n - s$ $\therefore$ $a + b = r - s + 2n$, and $a + b - 2n = r - s =$ leſs value of c, &c.

6. Corollary. Hence if $r - s = 1$, then n, a, b, &c. will be integers.

7. Example. Let $e = 3$, $r = 4$, and $s = 3$, then $a = 13$, $b = 6$, and $c = 1$, or 37, ſo that $c + e$, $b + e$, and $a + e$, are all ſquares.

Scholium. If the prob. had been to find $ab - e$, $ac - e$, and $bc - e$ all ſquares, the only alteration would be to change the ſign of e, or find $a = \frac{r^2 + e}{r - s}$, $b = \frac{s^2 + e}{r - s}$, and the leſs value of $c = r - s$, or the greater $=$ the exceſs of $2a + 2b$ above $r - s$ as before.

Prob. XXV.

42. To find four numbers, ſuch that, if 1 or any ſquare number be added to the product of every two of them, all the ſums may be ſquares.

1. Take a, b, and c, in arithmetical progreſſion, their common difference 1. Then if x, $a^2x + 2a$, $b^2x + 2b$, and $c^2x + 2x$ denote the four numbers ſought, every condition is anſwered, except $BD + 1 =$ ſquare. Let $a = 2$, $b = 3$, $c = 4$, then the four numbers ſought are x, $4x + 4$, $9x + 6$, and $16x + 8$, $BD + 1 = 64x^2 + 96x + 33$. Let $\overline{8x - 6}^2 = 64x^2 - 96x + 36$; $192x = 3$, and $x = \frac{1}{64}$.

3. Let $\overline{8x - 12}^2 = 64x^2 - 192x + 144$; $288x = 111$, and $x = \frac{111}{288} = \frac{37}{96}$. Let $\overline{8x - 9}^2 = 64x^2 - 144x + 81$; $240x = 48$, and $x = \frac{4}{20} = \frac{2}{10} = \frac{1}{5}$. Therefore, $\frac{2}{10}$, $\frac{48}{10}$, $\frac{78}{10}$, $\frac{112}{10}$, or, $\frac{1}{5}$, $\frac{24}{5}$, $\frac{39}{5}$, and $\frac{56}{5}$, are the numbers required, when 1 is the additive number. But if we ſuppoſe it ſome other ſquare number, as 100, and multiply each of theſe numbers by its root, we ſhall have 2, 48, 78, 112, for the numbers required.

Prob. XXVI.

43. To find x and y, when $x - y$, $x^2 - y^2$, and $x^3 - y^3$ are all ſquares. Aſſume $x - y = a^2$, and $x + y = m^2a^2$, or $x^2 - y^2 = m^2a^4 =$ a ſquare.

Now, $2x = m^2a^2 + a^2$, or $x = \frac{m^2a^2 + a^2}{2}$, and $y = \frac{m^2a^2 - a^2}{2}$. But $x^3 - y^3 = \frac{a^6 \cdot 3m^4 + 1}{4}$, or $3m^4 + 1$ muſt be made a ſquare; m muſt be $= 2$. Hence this

Rule. Take $x - y =$ any ſquare number, and $x + y =$ 4 times that number, and find x and y required.

Examples. Let $x - y = 4$, and $x + y = 16$, then $x = 10$, and $y = 6$, and the three expreſſions 4, 64, and 784.

Prob. XXVII.

44. To find three numbers in geometrical progreſſion ſuch, that a given number being added to each may make them all ſquares.

Let a^2, ax, and x^2 denote the three numbers ſought, and the firſt condition is ſatisfied.

Find two ſquares whoſe difference is s (24), and let the leſs $= a^2$, and the ſecond condition is ſatisfied. But $ax + s$, and $x^2 + s$, are alſo to be ſquares. Their difference is $x^2 - ax$. Factors x and $x - a$, the $\frac{1}{2}$ difference is $\frac{a}{2}$ $\therefore$ $\frac{a^2}{4} = ax + s$, or $ax = \frac{a^2}{4} - s =$ 2d number, and the third is found by proportion.

Ob. $ax = \frac{a^2}{4} - s$ muſt be affirmative $\therefore$ a^2 greater than $4s$. Whence this

Rule. Find two ſquares whoſe difference is s, and the leſs of them greater than $4s$, (30. 2.) call this leſs ſquare a^2; the mean term is $\frac{1}{4}a^2 - s$, and the other extreme is found by proportion.

Examples.

1. Find three numbers in geometrical progreſſion ſuch, that $21 = s$ added to each, may make the ſums ſquares. Factors 21 and $\frac{21}{21}$ and $\frac{1}{2}$ diff. $= 10\frac{1}{2} - \frac{1}{2} = 10$. The two ſquares are 121 and $100 = a^2$ greater than $4s = 84$ $\therefore$ 100 : 4 and $\frac{4}{25}$ are the numbers required.

2. Let $s = 19$, then 100 and $81 = a^2$ greater than $4s = 76$ and 81, $\frac{5}{4}$ and $\frac{25}{1296}$ are the numbers. Factors 19 and $\frac{19}{19}$ and $\frac{1}{2}$ diff. $= 9\frac{1}{2} - \frac{1}{2} = 9$.

Prob. XXVIII.

45. To find three ſquare numbers in arithmetical progreſſion.

Let, 1. $1 + 4d$, and $1 + 8d =$ denote the three numbers, then $1 + 4d$ and $1 + 8d$ are to be made ſquares.

Difference is $4d$, factors 2, and $2d$, $\frac{1}{2}$ ſum $d + 1$, and $d^2 + 2d + 1 = 1 + 8d$, or $d^2 - 6d = 0$, or $d = 6$, ſo that 1, 25, and 49 are the numbers. Or, let x^2, x^2y^2, and $2x^2y^2 - x^2$ denote the three ſquare numbers, then 1, y^2 and $2y^2 - 1$ are ſquares; and $y = 5$ $\therefore$ 1, 25, 49 multiplied by x^2, will give as many anſwers as we pleaſe.

Prob. XXIX.

46. To find three ſquare numbers in harmonical proportion, *i. e.* to find x^2, b^2, a^2; when as $x^2 : a^2 :: x^2 - b^2 : b^2 - a^2$. Aſſume two known ſquares for b^2 and a^2, ſuppoſe 49 and 25, then as $x^2 : 25 :: x^2 - 49 : 24$, or $24x^2 = 25x^2 - 1225$, or $x^2 = 1225$.

Prob. XXX. *vide* Prob. XXVIII.

47. Firſt find three ſquare numbers in arithmetical progreſſion, each of which will be the ſum of two of the numbers ſought, and have the ſame common difference as the numbers ſought.

Thus let x^2, $x^2 + 20y$, and $x^2 + 40y$, denote three ſquare numbers in arithmetical progreſſion. Then diff. $= (25.)\ 20y$, the factors $2y$ and 10, the $\frac{1}{2}$ diff. of them is $y - 5 = x$. Firſt $x^2 = \overline{y-5}^2 = y^2 - 10y + 25$ $\therefore x^2 + 20y = y^2 + 10y + 25$ = a ſquare; but $x^2 + 40y = y^2 + 30y + 25$ is alſo to be made a ſquare.

Aſſume $\overline{y+a}^2 = y^2 + 2ay + a^2$; $30y + 25 = 2ay + a^2$, or $30y - 2ay = a^2 - 25$, and $y = \frac{a^2 - 25}{30 - 2a}$; a is evidently limited between 5 and 15. Let $a = 13$, then $y = 36$, $20y =$ common diff. $= 720$, and $x = 31$. So that 961 = ſquare of 31, 1681 = ſquare of 41, and 2401 = ſquare of 49, are the three ſquares ſought, and from the ſum 961, and diff. 720, we find $120\frac{1}{2}$, $840\frac{1}{2}$, and $1560\frac{1}{2}$, the three numbers required. Or, by denoting the three required ſquares by x^2, $x^2 + 40y$, and $x^2 + 80y$, and proceeding as above, we have $y = \frac{a^2 - 100}{60 - 2a}$, a between 10 and 30; if $a = 26$, then $y = 72$, and $40y = 2880$, and $x = 62$, and the three ſquares, as well as the three numbers ſought, $= 4$ times thoſe above the ſmalleſt poſitive integral anſwer.

A more general ſolution may be had by denoting the required ſquares thus; x^2, $x^2 + 4ay$, and $x^2 + 8ay$, then $y^2 + 6ay + a^2$ is to be made a ſquare, aſſume $= \overline{y+ma}^2$ $= y^2 + 2may + m^2a^2$, and we ſhall have $y = \frac{m^2a^2 - a^2}{6a - 2ma}$ $= \frac{m^2a - a}{6 - 2m} = \frac{a \cdot \overline{m^2 - 1}}{6 - 2m}$, where m muſt evidently be between 1 and 3. If $m = \frac{13}{5}$, and $a = 5$, then $y = 36$, $x = 31$, &c. as above.

Prob. XXXI.

48. To find in whole numbers the three ſides of a triangle having one angle $= 120$. *Plate* VI. *Geometry*, *fig.* 84.

Lemma. When angle B $= 120°$, then $c^2 = a^2 + ab + b^2$. When $\angle$ B $= 60°$, then $c^2 = a^2 - ab + b^2$.

Demonſtration. 1. In A B produced, take B D $=$ B C $=$ C D. ſince $\angle$ C B D $= 60°$. Draw the perpendicular C E, then B E $= \frac{1}{2}b = \frac{1}{2}$ B C; but 47 . E . 1 . B E^2 + E C^2 = B C^2, or $\frac{1}{4}b$ + E C^2 $= b^2$, or E C^2 $= \frac{3b^2}{4}$. Now A E $= a + \frac{1}{2}b$, and A E^2 $= a^2 + ab + \frac{1}{4}b^2$ $\therefore$ 47 . E . 1 . A C^2 $= c^2 = a^2 + ab + b^2$.

2. Again; let A D $= a$, &c. as before; then A E $= a - \frac{1}{2}b$, and A E^2 $= a^2 - ab + \frac{1}{4}b^2$; or A C^2 $= c^2 = a^2 - ab + b^2$. Q. E. D.

Cor. 3.—If a, b, c, be the ſides of a triangle, and a and b contain an angle of 120°; then $a + b$, b and c are the ſides of a triangle, and $a + b$ and b contain an angle of $60° =$ A D C; and $a + b$, a and c are the ſides of a triangle, and $a + b$ and a contain an angle of $60° =$ C F A.

Cor. 4.—The ſame is true of any equimultiples of a, b, and c, as ad, bd, cd, &c.

Solution. 1.—Aſſume any number b for one of the containing ſides, and put $x =$ the other; then the ſquare of the third ſide is $b^2 + bx + x^2$ per lemma.

Aſſume it $= \overline{a-x}^2 = a^2 - 2ax + x^2$; or $a^2 - 2ax = b^2 + bx$, or $2ax + bx = a^2 - b^2$, and $x = \frac{a^2 - b^2}{2a + b}$. Therefore the three ſides are b, $\frac{a^2 - b^2}{2a + b}$, and $a - \frac{a^2 - b^2}{2a + b}$, or $\frac{2ab + b^2}{2a + b}$, $\frac{a^2 - b^2}{2a + b}$, and $\frac{a^2 + ab + b^2}{2a + b}$. Or (48. 4.) $2ab + b^2$, $a^2 - b^2$, and $a^2 + ab + b^2$ are the three ſides, all integers.

2. Put $s = a + b$, then $s^2 = a^2 + 2ab + b^2$, and $2ab + b^2 = s^2 - a^2$, and $a^2 + ab + b^2 = s^2 - ab$; whence this

Rule.—Take any numbers, a and b. whoſe ſum is s, then the containing ſides are $a^2 - b^2$, and $s^2 - a^2$, and the oppoſite ſide is $s^2 - ab$.

Example.—Let $a = 2$, $b = 1$, and $s = 3$, then 3, 5, and 7, are the ſides; or by taking the ſum of the leaſt ſides $3 + 5 = 8$, we have 5, 8, 7, or 3, 8, 7, for the ſides of two other triangles, having the angle oppoſite the ſide $7 = 60°$.

Moreover, the ſum of the ſquares +, the product of the containing ſides, is a ſquare. (per 48.)

Prob. XXXII.

49. To find in whole numbers, three right-angled triangles, having all the ſame area: the hypothenuſe is out of the queſtion.

1. Find (per 48.) the three ſides a, b, and c, of a triangle, having the angle oppoſite $c = 120°$, then of a and c, b and c, and $\overline{a+b}$, &c. form three right-angled triangles (per 21.) and they will all have the ſame area.

Demonſtration. 2. The triangle formed of a and c will have $c^2 - a^2$, and $2ac$ for its ſides, and $\therefore ac \cdot \overline{c^2 - a^2}$ for its area. But (per 48.) $c^2 = a^2 + ab + b^2$ $\therefore c^2 - a^2 = ab + b^2 = b \cdot \overline{a+b}$, and $ac \cdot \overline{c^2 - a^2} = acb \cdot \overline{a+b}$ = area of 1ſt triangle.

3. The ſides of the 2d triangle, from b and c, are $c^2 - b^2$ and $2bc$, and its area $bc \cdot \overline{b^2 - c^2}$; but $c^2 - b^2 = a^2 + ab$ $= a \cdot \overline{a+b}$ $\therefore bc \cdot \overline{c^2 - b^2} = bca \cdot \overline{a+b}$, the ſame as the area of the 1ſt triangle.

4. From $\overline{a+b}$ and c the ſides are $\overline{a+b}^2 - c^2 = a^2 + 2ab + b^2 - a^2 + ab + b^2 = ab$, and $2c \cdot \overline{a+b}$.

Therefore its area is $abc \cdot \overline{a+b}$, the ſame as the other two. Q. E. D.

Example.—The numbers in 48. were 3, 5, 7. Of 3 and 7 the triangle is 40 and 42, and area 840. Of 5 and 7 the triangle is 24 and 70, and area 840. Of 8 and 7 the triangle is 15 and 112, and area 840.

Prob. XXXIII.

50. To find three numbers a, b, and c, ſuch that s being their ſum $a^2 \pm s$, $b^2 \pm s$, and $c^2 \pm s$, may be all ſquare numbers.

1. The

1. The ſquare of the hypothenuſe $\pm$ the double product of the ſides = a ſquare, but the double product of the ſides = 4 times the area ∴ the ſquare of the hypothenuſe = 4 times the area = a ſquare number.

2. Find, (per 49.) three right-angled triangles having all the ſame area, and let their hypothenuſes be a, b, and c, let m = 4 times the common area, and $s = a + b + c$: then $a^2 \pm m$, $b^2 \pm m$, and $c^2 \pm m$, are all ſquare numbers.

3. Aſſume any indeterminate ſquare, as x^2; then $a^2 x^2 \pm m x^2$, $b^2 x^2 \pm m x^2$, and $c^2 x^2 \pm m x^2$ are ſquares. We have only to find ſuch a value of x, that $m x^2$ may be $= a x + b x + c x$ = the ſum of the three numbers: let $m x^2$ be $= a x + b x + c x$: then $x = \frac{a + b + x}{m} = \frac{s}{m}$. Therefore the three numbers $a x$, $b x$, $c x$, are $\frac{a s}{m}$, $\frac{b s}{m}$, and $\frac{c s}{m}$, reſpectively.

Example. 4. The three triangles having the ſame area in 49, are 40, 42, 58 — 24, 70, 74 — and 15, 112, 113 ∴ $a = 58$, $b = 74$, and $c = 113$, $s = 245$, $m = 840.4 = 3360$, and $\frac{s}{m} = \frac{245}{3360} = \frac{49}{672} = \frac{7}{96}$ ∴ $\frac{406}{96}$, $\frac{518}{96}$, and $\frac{791}{96}$, are the three numbers required: for their ſum is $\frac{1715}{96} = \frac{164640}{9216}$ and $\overline{\frac{400}{96}}^2 = \frac{164836}{9216}$ and $\frac{164836 \pm 16460}{9216} = \frac{329476}{9216}$ or $\frac{196}{9216}$ the ſquares of $\frac{574}{96}$, or $\frac{14}{96}$, &c.

PROB. XXXIV.

51. To find three ſuch numbers that the ſum or difference of any two of them may be a ſquare.

1. Aſſume $4x$, $4 + x^2$, and $1 + 4x^2$, for the three numbers ſought: then the ſum and difference of the firſt, and each of the others, are ſquares: it remains to make the ſum and difference of the two laſt ſquares. We are to make $5x^2 + 5$, and $3x^2 - 3$, ſquares; their product $15x^4 - 15 = 15 . x^4 - 1$ muſt be a ſquare. If $x = 2$, it is $15 . \overline{16 - 1} = 15 . 15$ evidently a ſquare, and the three numbers 8, 8, and 17: the firſt and ſecond the ſame.

2. Put $x = z - 2$, then $15x^4 - 15 = 225 - 480z + 360z^2 - 120z^3 + 15z^4$ = a ſquare, ſuppoſe $= \overline{15 - az + bz^2}^2 = 225 - 30az + \left\{\begin{matrix} 30b \\ a^2 \end{matrix}\right\} z^2 - 2abz^3 + b^2 z^4$, where it is evident that the co efficients of the correſponding powers of z muſt be equal, elſe all the terms brought to one ſide could not be = 0. From $30a = 480$, we have $a = 16$; from $30b + a^2 = 360$, $30b = 104$; and $b = \frac{52}{15}$, and from $15z^4 - 120z^3 = b^2 z^4 - 2abz^3$, $15z - 120 = b^2 z - 2ab$; $15z - b^2 z = 120 - 2ab$, and $z = \frac{120 - 2ab}{15 - b^2} = \frac{2040}{671}$ ∴ $x = z - 2 = \frac{2040}{671} - \frac{1342}{671} = \frac{698}{671}$. Which, ſubſtituted in the aſſumed expreſſions, gives $4 . \frac{698}{671}$, $4 + \overline{\frac{698}{671}}^2$, and $1 + 4 . \overline{\frac{698}{671}}^2 = \frac{2792}{671}$, $\frac{2288168}{\overline{671}^2}$, and $\frac{2399057}{\overline{671}^2}$; or, rejecting the common denominator, we have the numbers ſought.

PROB. XXXV.

To find the leaſt biquadratic number, that can be divided into four integral parts, ſuch that the ſum of every two of them may be a ſquare number.

Let n^4 denote the biquadratic number ſought, and a, b, c, and d, its four integral parts, then the queſtion requires, that $a + b = \mu^2$, $a + c = \mu'^2$, $a + d = \mu''^2$, $c + d = \nu^2$, $b + d = \nu'^2$, and $b + c = \nu''^2$. Hence we get $n^4 = a + b + c + d = \mu^2 + \nu^2 = \mu'^2 + \nu'^2 = \mu''^2 + \nu''^2$.

We ſee, therefore, that the biquadratic number ſought muſt be reſolvable into three ſquares, three different ways, and this condition being fulfilled, we derive

$a = \frac{1}{2}(\mu^2 + \mu'^2 - \nu''^2)$, $b = \frac{1}{2}(\mu^2 + \nu''^2 - \mu'^2)$

$c = \frac{1}{2}(\mu'^2 + \nu''^2 - \mu^2)$, $d = n^4 - \frac{1}{2}(\mu^2 + \mu'^2 + \nu''^2)$,

from which formulæ it may be inferred, that the three ſquares μ^2, μ'^2, and ν''^2, muſt either be all even, or two of them muſt be odd and only one even, in order that no fractions may ariſe from the diviſions by 2, and likewiſe that the ſum of every two of them muſt be greater than the third; and, at the ſame time, the ſum of all three leſs than $2n^4$, in order to avoid negative numbers.

It is then neceſſary to find a biquadratic number that may be divided into two ſquares three different ways. We owe to Fermat the curious diſcovery, that every prime number, exceeding a multiple of 4, by unity, or comprehended in the form $4x + 1$, is the ſum of two ſquares; and this property, which is univerſal for prime numbers of the form $4x + 1$, belongs excluſively to that form, ſo that no prime number, which is not of the form $4x + 1$, can poſſibly be the ſum of two ſquares. This curious propoſition was firſt demonſtrated by the celebrated Euler, and to effect the demonſtration, it was neceſſary to prove this other propoſition, *viz.* that every diviſor of a number, which is the ſum of two ſquares that are prime to one another, is likewiſe the ſum of two ſquares. From theſe principles we may eaſily gather, that the biquadratic number, n^4, which we are ſeeking, muſt have prime diviſors of the form $4x + 1$; for if it had none, it could not poſſibly be the ſum of two ſquares: and as the leaſt value of n^4 is required, we may ſet aſide all other diviſors; for if n^4 had any other diviſors, theſe could only enter as common meaſures, into every two ſquares that

compoſe n^4. We may, therefore, ſuppoſe n^4, and conſequently n, to have no diviſors, but prime numbers of the form $4x + 1$; and, in the firſt place, let us ſee whether a prime number p, of the form $4x + 1$, will anſwer for n. We have already mentioned, that p is the ſum of two ſquares, $\alpha^2 + \beta$; and we have now to add, that p can be the ſum of two ſquares only one way. In like manner, we find $p^2 = (\alpha^2 + \beta^2)^2 + 4\alpha^2\beta^2$, nor can p^2 be reſolved into two ſquares any other way. Proceeding to the fourth power, we ſhall find $p^4 = (\alpha^4 - 6\alpha^2\beta^2 + \beta^4)^2 + (4\alpha^3\beta - 4\alpha\beta^3)^2$, $p^4 = p'^2\alpha^2 + p^2\beta^2$. All theſe two are all the ways that p^4, that be reſolved into two ſquares, therefore no ſingle prime number, of the form $4x + 1$, will anſwer the conditions required. Let us now try the product of two prime numbers of the ſame form as p and p'; then, according to what has been ſhewn, we ſhall have

$p^4 = (\alpha^4 - 6\alpha^2\beta^2 + \beta^4)^2 + (4\alpha^3\beta - 4\alpha\beta^3)^2$,
$p^4 = p'^2\alpha^2 + p^2\beta^2$; and in like manner
$p'^4 = (\alpha'^4 - 6\alpha'^2\beta'^2 + \beta'^4)^2 + (4\alpha'^3\beta'^3 - 4\alpha'\beta'^3)^2$,
$p'^4 = p''^2\alpha'^2 + p'^2\beta'^2$: therefore, combining the two values of p^4 with the two values of p'^4, the biquadratic $p^4p'^4$ will be the product of the ſums of two ſquares four different ways; but the product of two ſums of two ſquares, is the ſum of two ſquares twice; for $(M^2 + N^2).(P^2 + Q^2) = (MP + NQ)^2 + (MQ - NP)^2 = (MP - NQ)^2 + (MQ + NP)^2$.

Therefore, by combining the two values of p^4 with the two values of p'^4, the biquadratic p'^4p^4 will be the ſum of two ſquares no leſs than eight different ways. To theſe eight we may add four other ways, by combining p^4 with the two values of p'^4, and p'^4 with the two values of p^4. Therefore the fourth power of a number which is the product of two primes of the form $4x + 1$ is the ſum of two ſquares no leſs than twelve different ways.

We ſee then, that no prime number of the form $4x + 1$, can ſatisfy the conditions required in the queſtion, but a number which is the ſum of two ſuch primes is the ſum of two ſquares twelve different ways, one ſquare of each ſum being even and one odd. Therefore, as every combination of three out of the twelve will give one ſolution of the queſtion, and as twelve numbers admit of 220 combinations of three, there will be ſo many different ſolutions, unleſs ſome are excluded as producing negative numbers. It is eaſy to ſee that one combination of three will only give one integral ſolution.

The two laſt primes of the form $4x + 1$ are 5 and 13, and their product 65, is conſequently the leaſt number that will ſatisfy the queſtion. We have $5 = 2^2 + 1$, and $13 = 3 + 2^2$. Whence $65^4 = 3713^2 + 2016^2$
$65^4 = 3047^2 + 3696^2$
$65^4 = 2145^2 + 3640^2$;
which are only three of the twelve ways that 65^4 is the ſum of two ſquares. And taking the three even ſquares for μ, μ', and ν'', our formulæ give $a = 1826720$, $b = 2237536$, $c = 11422880$, and $d = 2363489$, which is one ſolution. In like manner, if we take another three of the twelve ways that 65^4 is the ſum of two ſquares, as
$65^4 = 2047^2 + 3696^2$
$65^4 = 2145^2 + 3640^2$
$65^4 = 4095^2 + 1040^2$ we ſhall derive another ſolution; $a = 740208$, $b = 12914208$, $c = 335392$, and $d = 3854817$.

DIOPHANTUS, in *Biography*, a celebrated mathematician and analyſt of Alexandria, who flouriſhed at a period which has not been preciſely aſcertained. According to Abulpharagius, in his "Hiſt. Dynaſt." he flouriſhed under the emperor Julian, or towards the year 366 of the Chriſtian era. It is certain that he could not be later than this time, becauſe the ingenious female Hypatia commented on his work; and it is well known that ſhe flouriſhed towards the commencement of the fifth century. Hypatia alſo commented on the "Canon aſtronomicus," which is juſtly aſcribed to this author. Such was his reputation among the ancients, that they ranked him with Pythagoras and Euclid, in reſpect to mathematical learning. Bachet de Méziriac has collected from Diophantus's epitaph, in the Greek Anthologia, which furniſhes a kind of arithmetical problem, the following particulars of his life: *viz.* that he was married when he was 33 years old, and had a ſon five years after; that this ſon died at the age of 42, and that his father did not ſurvive him above four years: whence it appears, that Diophantus was 84 years of age when he died. The problem amounts to this: to find a number ſuch that its 6th, 12th, 7th parts with five, its half and four amount to *the whole* number, which is evidently 84. He is ſaid to have been the inventor of algebra, or at leaſt he is the firſt of the Greeks who has written on this ſubject. Although we ſhould not be warranted in aſcribing the invention of algebra to Diophantus, he introduced the uſe of various ſymbols into this ſcience. He denotes the unknown number by $\sigma\tau\iota$; its ſquare he called $\delta\upsilon\nu\alpha\mu\iota\varsigma$ or power, and he marked it by δ^{ν}; the cube he called $\kappa\upsilon\beta\circ\varsigma$, and diſtinguiſhed it by κ^{ν}: the biquadrate by $\delta\delta^{\nu}$; the fifth power by $\delta\kappa^{\nu}$. But the diſcovery which demands our more particular attention was the method adopted by Diophantus, of applying the algebraic analyſis to indeterminate problems. (See the preceding article.) He wrote ſix books of arithmetic, or algebra, which Regiomontanus, in his preface to Alfraganus, informs us, are ſtill preſerved in MS. in the Vatican library. Indeed we learn from Diophantus himſelf, at the cloſe of his addreſs to Dionyſius, prefixed to his work, that it conſiſted of 13 books; whence Regiomontanus might infer that the 13 books were in that library. But no more than ſix books, with part of a ſeventh, have ever been publiſhed; and it may be preſumed that no more are extant. Bombelli, in the preface to his Algebra, written in the year 1572, ſays, that there were but ſix of the books then in the library. Theſe ſix books, with the imperfect ſeventh, were firſt publiſhed at Baſil by Xylander, in the year 1575, in a Latin verſion, with the Greek ſcholia of Maximus Planudes upon the two firſt books, and obſervations of his own. The ſame books were afterwards publiſhed in Greek and Latin at Paris, in 1621, by Bachet, who made a new Latin verſion, and added learned commentaries. He paid ſome regard to Xylander's notes, but treated thoſe of the ſcholiaſt Planudes with the utmoſt contempt. He ſeems to intimate, that the ſix books of Diophantus, now extant, may be merely a collection made by ſome novice of ſuch propoſitions, as he thought proper to ſelect out of the whole 13; but Fabricius thinks that his ſuppoſition is altogether unfounded. M. de Fermat made ſome notes on the edition of Bachet, which was republiſhed by his ſon in 1670. Father de Belli, a jeſuit, publiſhed a work under the title of "Diophantus Redivivus," containing queſtions of more difficult ſolution than thoſe of the ancient analyſt. The ſame ſubject has engaged the attention of Ozanam, Preſtet, Kerſey, M. de Lagni, Frenicle, Wallis, Saunderſon, Euler, Playfair, Ivory, &c.—Montucla, Hiſt. Math. vol. 1.

DIOPOLIS, in *Ancient Geography*, a town of Aſia, in Armenia Minor, formerly called *Cabira*, and afterwards *Sebaſte*.

DIOPSIS, in *Entomology*, a genus of the dipterous order of

of inſects, generically diſtinguiſhed by having the eyes placed at the tip of two long filiform immoveable horns, which project from the head, inſtead of being ſeated, as in other inſects, within the head itſelf. Of this moſt ſingular genus we are acquainted with two ſpecies; one, the example deſcribed by Linnæus, under the ſpecific name of Ichneumonea; the other, non-deſcript. Linnæus, to whom only the firſt ſpecies was known, as uſual with him under ſuch circumſtances, does not aſſign any ſpecific character; the following is taken from Mr. Donovan's ſplendid illuſtration of the inſects of India, in which this extraordinary inſect is deſcribed at conſiderable length, with an appropriate accompaniment of figures.

"*Diopſis Ichneumonea:* nigra capite abdomine antice pedibuſque ferrugineis, thorace poſtice biſpinoſo."—"Black; head, anterior part of the abdomen and legs ferruginous: two ſpines on the poſterior extremity of the thorax."—"The appearance of this curious inſect is peculiarly ſtriking. Nothing can be more ſingular than the diſpoſition of the eyes, which are ſituated at the extremity of two long immoveable pedicles ariſing from the head, moſt exactly in that part which in other inſects bears the antennæ. In this particular the diopſis differs not only from other inſects of the kindred genera, but alſo from all other kinds we are acquainted with. Some few of the cancri (which Linnæus admits among the inſect race) have indeed the eyes placed at the extremity of elongated pedicles, as is for example inſtanced in the cancer angulatus; yet theſe are obviouſly diſſimilar in conſtruction, for they are moveable at the baſe, and may be directed towards any object at the will of the animal with the utmoſt facility; but, to accompliſh this, the motion of the pedicle in the diopſis muſt be neceſſarily accompanied by that of the head, or even of the whole body. The eyes of the latter are notwithſtanding ſo conveniently ſtationed at the globular extremity of the pedicles, as to embrace a far more comprehenſive range of ſight than is uſual in the generality of inſects.

"To the inexperienced entomologiſt, the diopſis would rather ſeem to be furniſhed with remarkable horns, and be deſtitute of eyes, although the latter are ſo conſpicuous when their ſituation is pointed out; it is, on the contrary, the true horns or antennæ that are ſo minute as to be moſt likely to eſcape attention, for each of theſe conſiſts only of a ſingle ſetaceous hair or briſtle ſeated on a very ſmall tubercle juſt beneath the eye.

"It has been previouſly intimated that the firſt account of the diopſis was given by Linnæus: it is inſerted in a ſmall tract, publiſhed at Upſal in 1775. From this we learn, that the diopſis was firſt obſerved by Andreas Dahl, among a parcel of inſects, in the poſſeſſion of Dr. Fothergill of London, by whom they were ſent to Linnæus. They conſiſted chiefly of inſects collected in North America and Guinea, but the habitat of the diopſis in particular was by no means exactly known. Fueſly, notwithſtanding, deſcribes the latter upon this ambiguous authority only as a native of Cayenne; and after him, Gmelin notes the ſame inſect from South America and Guinea, perhaps with as little reaſon. Latreille tells us, it is from the coaſt of Angola, on the information of Perrin, a zealous naturaliſt of Bourdeaux. Our ſpecimens were brought from Bengal; it was diſcovered by Mr. Fichtel, who has thus eſtabliſhed the habitat of this ſingular creature beyond diſpute." Vide *Inſ. India.*

This inſect is rather larger than the common houſe-fly, and is very ſcarce.

DIOPTER, or DIOPTRA, in *Writers of Aſtronomy*, is frequently uſed for the hole, or index, pierced in the pinnula, or ſight of an alhidade. See SIGHTS.

DIOPTRA, among the *Ancients*, an inſtrument invented by Hipparchus, which ſerved for ſeveral uſes, as to level water, to take the height of towers, or places at a diſtance; to determine the places, magnitudes, and diſtances of the ſtars.

DIOPTRA, among *Surgeons*, denotes an inſtrument whereby to dilate the matrix, or anus, and inſpect any ulcers therein; called alſo ſpeculum matricis and dilatatorium.

DIOPTRICS (from the Greek διοπτομαι, to ſee through) is a branch of the ſcience of optics, and treats of the different refractions of light paſſing through different mediums, ſuch as glaſs, water, air, &c.—When the rays of light paſs in an oblique direction from one medium into another, their direction, which is otherwiſe ſtraight, is generally bent at the point of tranſition, and that bending is called the *refraction of light*, the quantity of which differs in different mediums.

In their tranſition from one medium into another, the rays of light, beſides their being bent or refracted, ſuffer a ſort of decompoſition, or a ſeparation of their component parts, whence ſeveral remarkable phenomena ariſe. It is the object of dioptrics to ſtate and to examine all theſe particulars, together with the various and important uſes to which they are applied. The rain-bow, the colours of thin tranſparent plates, the apparent deviation of the celeſtial objects from their true ſituations, and various other natural phenomena, ariſe from the refraction of light; the action of the teleſcopes and microſcopes that are conſtructed with glaſs lenſes, the action of the camera obſcura, of ſpectacles, and of lenſes in general, together with that of all the inſtruments that contain lenſes, depend entirely upon the refraction of light. However, agreeably to the plan of this dictionary, we ſhall only treat of the general theory of dioptrics in the preſent article; but we ſhall deſcribe the rain-bow, the teleſcope, camera obſcura, magic lantern, &c. under the articles of their reſpective denominations. When the rays of light paſs obliquely from any tranſparent ſubſtance into a vacuum, or from the latter into the former, or, in general, from one tranſparent medium into another tranſparent ſubſtance of different denſity, then they are *refracted* (*viz.* bent) at the point of inſertion. But if, inſtead of falling obliquely on the ſurface of any medium, they fall perpendicularly upon it; or if they continue in the ſame medium, then they proceed in ſtraight lines without any perceptible deviation one way or another. The light of the celeſtial objects, in its paſſage through the atmoſphere to our eyes, has been found to move in curves, which is owing to the various denſities of the air at different diſtances from the ſurface of the earth. The refraction of light may be illuſtrated by the following eaſy and familiar experiments.

1. Provide a glaſs veſſel A B C, (*Plate* IV. *Optics, fig.* 2.); lay a card, having a ſmall hole F in its middle, upon the aperture of it, and fix a candle or lamp E above the veſſel, ſo that its flame may ſtand perpendicularly over the hole F in the card, which may be eaſily accompliſhed by means of a plummet. In this ſituation of the apparatus the image of the hole will be caſt at D, upon the bottom of the veſſel; and the line which paſſes through the flame E, the hole F, and the image D, will be a ſtraight line, as may be determined by holding the plummet on one ſide of the veſſel. Now, without altering any part of the apparatus, let the glaſs veſſel A B C be filled with water, which done, it will be found that the image of the hole remains at its original place D; which ſhews that the light of the flame E, paſſing through the hole F, and falling *perpendicularly* upon the ſurface W S of the water, proceeds in a ſtraight line to D, without ſuffering any bending or refraction at the point of its entrance into the water.

2. Take a veſſel A B D C, *fig.* 3. open at top, place a lighted

a lighted candle on one ſide of it, and a little above the upper edge of it, as at G, and the edge of the ſhadow of the ſide of the veſſel B will be found to fall upon the bottom at E, ſo that the line G B D may be a ſtraight line. Now, without diſturbing any part of the apparatus, let the veſſel A B C D be filled with water, and when this has been done you will find that the edge of the ſhadow falls at F, *viz.* at a place different from D, which proves beyond a doubt, that the light which falls obliquely upon the ſurface of the water at B is refracted, *viz.* bent by it; for if it proceeded in a ſtraight line, G B F would coincide with G B D, which is by no means the caſe.

3. An eaſier way of ſhewing this remarkable property of light is as follows. Place a piece of money D, *fig.* 4. in the bottom of a common empty baſon, and let a perſon ſituate his eye at F; *viz.* at a place whence he may juſt ſee the piece of money D along the edge B of the veſſel. In this caſe the line F B D is a ſtraight line, becauſe the light from the piece of money D to the eye at F paſſes entirely through air. Now let the obſerver place his eye a little below F, as at G, and from this latter place he will not be able to ſee the piece of money; but if in this diſpoſition of the apparatus, eye, &c. the baſon be filled with water, the eye at G will immediately perceive the piece of money; for the ray of light D B, in paſſing from the water into the air at B is bent, *viz.* refracted into the direction B G.

At the point B of *fig.* 3. raiſe B K perpendicular to the ſurface of the water, and let the line B I be a prolongation of that ſurface, or an horizontal line. Then the ray of light G B, which falls upon the ſurface of the water at B, is called the *incident ray*; that part of it B F, which after the bending at B, paſſes through the water, is the *refracted ray*; the water, or any other tranſparent ſubſtance, which produces a ſimilar effect, is called the *refracting medium*; the angle which the incident ray G B makes with the perpendicular to the ſurface at the point of incidence B; *viz.* the angle G B K is the angle of incidence, the angle which the refracted ray makes with the ſame perpendicular produced; *viz.* the angle G B F, is the angle of refraction. But ſome authors call G B I the angle of incidence; and F B A, the angle of refraction; which are the angles made by the incident and the refracted rays, with the ſurface or horizontal line A B I.

Inſtead of water, the veſſel A B D C, *fig.* 3. may be filled with oil, or with ſpirit of wine, or with a lump of glaſs, or in ſhort with any other tranſparent medium different from air, and the ray of light G B will always be bent; with this difference, however, that the ray will be bent, *viz.* refracted, more or leſs according as one tranſparent medium or another is employed; which ſhews that every tranſparent ſubſtance has a peculiar degree of refracting power. And accordingly if the experiment be ſucceſſively repeated with different refracting mediums, and the place of the edge of the ſhadow on the bottom of the veſſel, be marked at each experiment; then from the diſtances of thoſe places, or marks from the point C, the reſpective refractive powers of the tranſparent ſubſtances that have been employed, may be determined. As a matter not of mere curioſity, but of very great uſe in the conſtruction of optical inſtruments, as well as in the inveſtigation of natural phenomena, theſe different refractive powers of tranſparent ſubſtances, have been attentively determined by various able philoſophers. A liſt of thoſe powers as belonging to different ſubſtances, together with the beſt methods of aſcertaining them, will be found under the article REFRACTION.

A remarkable property has been obſerved with reſpect to the refractive power of tranſparent ſubſtances, which is that in the ſame ſubſtance the ſine of the angle of refraction always bears the ſame proportion (either preciſely or very nearly) to the ſine of the angle of incidence. This requires illuſtration by means of a diagram. Let F G H Z (*fig.* 5.) be a quantity of water; B is a narrow tube through which the ſun ſhines obliquely upon the water at C. Then, on account of the refractive property of water, that light will not paſs through the water along the line C Z, which is in the ſame ſtraight direction with B C; but it will paſs in the direction C D; making the angle of refraction D C E, with the line A C E (which is perpendicular to the ſurface of the water, or to the boundary of the two mediums, *viz.* water and air) ſmaller than the angle of incidence A C B. Let a circle F H E be deſcribed about the centre or point of incidence C, in the ſame plane with the lines B C, C D; and from the interſection H of the circle with the incident ray, let a perpendicular H K be dropped on the line A E; then H K is the ſine of the angle B C A. Alſo, if from the interſection I of the circle with the refracted ray, a perpendicular I L be dropped on the ſame line A E, then I L will be the ſine of the angle D C E.

Now it has been found that the ſine I L is always nearly three-fourths of the ſine H K, let that ſine be what it may; for inſtance, if the tube B be placed at M, then O R will be the ſine of the angle of incidence M C A; and Y Q will be the ſine of the angle of refraction, or of the angle in water Y C E. And in this caſe it will be found, as above, that the ſine Y Q is nearly three-fourths of the ſine O R.

It is evident, that when the incident ray comes along the line A C, the angle of incidence, as well as its ſine, vaniſhes or becomes nothing; conſequently, the angle of refraction and its ſine, muſt vaniſh too; *viz.* the ray of light muſt proceed ſtraight along the line A C E; hence it is ſaid that there is no refraction when the rays of light enter a medium in a direction perpendicular to its ſurface.

If inſtead of water, F G H Z be ſuppoſed to be a lump of glaſs, every thing elſe remaining as above; then the difference in the reſult would be, that the ratio of the ſine of refraction to that of incidence would be that of 2 to 3; (inſtead of being that of 3 to 4, which is the caſe with water) *viz.* the angles of refraction will be reſpectively ſmaller when F G H Z is glaſs than when it is water. And if inſtead of water or glaſs, F G H Z were a diamond, then the angle of refraction would be ſmaller ſtill; *viz.* the ſine of the angle of refraction in the diamond would be to the ſine of the angle of incidence in the air, nearly as 2 to 5. Hence it appears, that the power of bending or refracting the rays of light is ſtronger in glaſs than in water, and ſtronger in diamond than in glaſs. See the article REFRACTION. The refractive property of tranſparent ſubſtances, and eſpecially of fluids, is increaſed a little, when their temperature is raiſed. Two other remarkable phenomena accompany the refraction of light, the firſt of which is that the light is not only bent whenever it paſſes obliquely from one medium into another of different denſity, but is likewiſe enlarged in a ſectoral, or fan-like, manner. The ſecond is that this enlarged part of the refracted light is tinged with the colours of the rainbow. In *fig.* 6, I C repreſents a ſmall beam of ſolar light, which paſſes through the air, and enters another refracting medium at C. There the beam of light is refracted, *viz.* is diverted from its ſtraight line direction I C, and is ſpread, or diſperſed, into the ſectoral ſhape *v* C *r*, which is called *the angle of diſperſion*, or *of diſſipation*, and which is itſelf divided into ſmaller ſectors of different colours; *viz.* next to the upper line C *r*, the light appears red, and thence it gradually degenerates into orange, then yellow, green,

blue

blue, indigo, and laſtly violet, which ſtands neareſt to the lower line or boundary C *v*. This diſperſion of the beam of light is in the ſame plane with the incident and the refracted ray I C *m*. The line C *m*, drawn through the middle of the angle of diſperſion *v* C *r*, is the mean direction of the refracted light, and *m e* is its ſine, which is called *the ſine of the mean angle of refraction*: *v f*, and *r d*, are the ſines of the extremes; *v f* being called *the ſine of the moſt refrangible colour, viz.* of the violet, and *r d*, *the ſine of the leaſt refrangible colour*, which is the red. This ſeparation of the white, or colourleſs light, into various colours, juſtly induced ſir Iſaac Newton to conclude, that white light conſiſts, or is a mixture, of differently coloured rays, which, being differently refrangible, are of courſe ſeparated by the refracting medium.

Through the ſame refracting medium the angle of diſperſion is always proportionate to the mean angle of refraction; conſequently when the mean angle of refraction is very ſmall, then the angle of diſſipation muſt be comparatively much ſmaller, in which caſe the different colours of the refracted light cannot be diſcerned; but when the angle of incidence, and of courſe the mean angle of refraction, is conſiderably large, then the angle of diſſipation will be ſo large as to exhibit the different colours. In order to render this coloured diſperſion of light as apparent as poſſible, philoſophers generally receive the light, either of the ſun or of any other luminous object, upon the ſide of a priſmatic lump of glaſs; for in that caſe the light, entering into and going out of the priſm with a great angle of inclination, its refraction and its diſperſion become very great; conſequently its colours, or as it is commonly called, *the priſmatic ſpectrum*, is broad and vivid. Hence the above-mentioned colours, or the component coloured rays of white light, have likewiſe been called *the priſmatic colours*. See PRISMATIC *Colours*.

Different refractive mediums have different diſperſive powers; for inſtance, the angle of incidence I C H, *fig.* 6. remaining the ſame, not only the mean angle of refraction *m* C E will vary according as the refractive medium A B D G is water, or glaſs, or oil, or other tranſparent ſubſtance; but the angle of diſſipation *v* C *r* will alſo vary. And in ſome refracting mediums the mean angle of refraction is larger, whilſt the angle of diſperſion is ſmaller. In other refracting mediums the mean angle of refraction is ſmaller, whilſt the angle of diſperſion is larger. In ſhort the knowledge of the mean refractive power of any given ſubſtance, will not enable us to determine the preciſe quantity of its diſperſive power, and *vice verſâ*. Therefore, in each particular tranſparent ſubſtance, both its refractive and its diſperſive properties muſt be aſcertained by means of actual experiments.

There is a remarkable ſort of tranſparent mineral bodies, which have the ſingular property of refracting the light in a double, and even in a multiple, direction; ſo that an object, ſeen through a plane plate of the tranſparent mineral, will appear double, and ſometimes even treble and quadruple. Rock cryſtal, and eſpecially the Iceland cryſtal, beſides a few other bodies, are poſſeſſed of this double, or even multiple refractive power.

A liſt of the diſperſive powers of various tranſparent ſubſtances will be found annexed to the liſt of refractive powers, under the articles REFRACTION, and DISPERSION, to which we refer our readers. We ſhall, however, here add a few uſeful and general remarks on refraction, &c.

Upon the whole it appears, that the denſer bodies; *viz.* thoſe which have a greater ſpecific gravity, refract, or bend, the rays of light, more than thoſe which are leſs denſe; excepting (as ſir Iſaac Newton expreſſes it) that unctuous and ſulphurous bodies refract more than others of the ſame denſity. There is no ſubſtance that has an intermediate refractive power between air and rain water, or diſtilled water. The refractive power of the diamond exceeds that of any other known ſubſtance, and to this property its peculiar brilliancy, when properly ſhaped, is in great meaſure to be attributed. Spirituous liquors have a greater refractive power in proportion to their ſtrength. Spirit of turpentine is the moſt refractive amongſt the fluids.

The above-mentioned properties of tranſparent bodies, or of light, or of both, however trifling they may appear to the novice in philoſophy, have proved extremely uſeful to the human ſpecies. Sir Iſaac Newton, who firſt paid particular attention, and made ſeveral important diſcoveries relative to the coloured rays of white light, had no ſuſpicion of the laſt above-mentioned property of tranſparent ſubſtances. He thought that the diſperſive power was conſtantly proportionate to the refractive. Experiments made ſubſequent to his, have ſhewn, that the fact is otherwiſe; ſo much ſo, that even glaſſes formed of different materials, or of the ſame ingredients in different proportions, are poſſeſſed of different diſperſive powers with the ſame refractive property, or of different refractive powers, and an equal diſperſive property. By a combination of lenſes conſiſting of different kinds of glaſs, the famous Dollond formed his achromatic object lenſes of teleſcopes; whence thoſe optical inſtruments received a moſt capital improvement; the nature of which may be briefly pointed out in this place, whilſt the detail of particulars will be found under the articles ACHROMATIC, and LENSES.

A glaſs lens, ſuch as is uſed for teleſcopes, bends the rays of light towards a particular point or ſmall ſpot, which is called its *focus*; but this bending of the rays of light is accompanied with a decompoſition of the ſame into their coloured component rays; therefore, the magnifying powers of the lenſes of the old teleſcopes were always attended with tints of the various priſmatic colours, which became more apparent in proportion as the magnifying power was greater, under a given length of teleſcope; hence thoſe teleſcopes could not be made to magnify the object beyond a very moderate degree; nor could their object lenſes have a large aperture. But Mr. Dollond formed each object lens by placing two, or three lenſes, cloſe to each other, which were made of different ſorts of glaſs, and ſuch as the diſperſive and refractive powers of one of them, ſhould counteract the diſperſive and refractive powers of the other; whence the compound lens might produce the effect of bending the rays of light to a focus, and at the ſame time not decompoſe them into their coloured parts. And from this effect the achromatic lenſes, or the achromatic teleſcopes, have derived their diſtinctive appellation. This ſort of teleſcope, then, has a vaſt advantage over thoſe of the old conſtruction; for ſince the effect of its object lens is not tinged with colours, the power of the teleſcope may be increaſed to a conſiderable degree, and its object lens may be made conſiderably larger, in conſequence of which the inſtrument will repreſent the objects very bright. In fact, a modern achromatic teleſcope of about four feet in length, and properly conſtructed, may be reckoned about equal in effect to a forty feet teleſcope of the old conſtruction.

We might now proceed to explain ſeveral natural phenomena, as alſo the nature and the effects of glaſs lenſes, of priſms, of teleſcopes with lenſes, and various other optical inſtruments, which undoubtedly belong to the dioptric branch of optics, but it has already been mentioned, that theſe will be found deſcribed under the articles of their particular names.

DIOPTRIC *Teleſcope*, is a teleſcope through which the light paſſes directly from the object to the eye of the obſerver. See DIOPTRICS.

Towards the cloſe of the 16th century, the wonderful diſcovery of the teleſcope was accidentally made by placing two glaſs lenſes at the two extremities of a tube, and looking through it. This diſcovery was no ſooner made, than the ingenuity of philoſophers began to vary and to improve the conſtruction, in order to render the inſtrument as powerful as poſſible, and to adapt it to the numerous purpoſes which it was juſtly thought capable of anſwering. But it being found that teleſcopes of this kind had a very limited power on account of the diſperſive power of the lenſes, and which at that time was looked upon as an unſurmountable obſtacle, (ſee DIOPTRICS) ſir Iſaac Newton firſt conſtructed a teleſcope, which inſtead of an object glaſs lens, had a reflector; whence the rays of light, inſtead of being *refracted* to a focus, were *reflected* to a ſocus; and this latter caſe was not attended with a diſperſion of the light into its coloured component rays, whence Newton's contrivance was thought capable of a much greater magnifying power, and altogether capable of greater improvements; which, in fact, has been verified through the aſſiduous exertions of philoſophers and artiſts. This contrivance introduced the different denominations of the *refracting* or *dioptric* teleſcope, and of the *reflecting* or *catadioptric* teleſcope. The former of theſe two kinds, which conſtitutes the object of the preſent article, conſiſts entirely of lenſes fixed in a tube or tubes; but the form, the number, and diſpoſition of theſe lenſes, has been much varied in order to render the inſtrument ſubſervient to different purpoſes. And according to its various conſtructions, and its various uſes, the dioptric teleſcope has obtained various particular appellations, which we ſhall briefly enumerate in this place; for their peculiar conſtructions, their powers, uſes, &c. will be found minutely deſcribed under the articles of their particular denominations.

The *aſtronomical* teleſcope conſiſts of two, either ſingle or compound, lenſes. It repreſents the objects inverted, and is principally uſed for obſerving the celeſtial bodies. When this ſort of teleſcope is very long, the two lenſes are connected together not by a tube, but by a ſtring or pole, and in that caſe it is called an *aerial* teleſcope.

By adding two or more convex lenſes to the eye tube of the aſtronomical teleſcope, that inſtrument is enabled to repreſent the objects erect, in which caſe it may more particularly be uſed for viewing land objects; whence it has been called a *perſpective glaſs*, or the *terreſtrial* teleſcope.

The *Galilean* teleſcope, contrived by the great Galileo, conſiſts of two lenſes; but the eye lens is a concave one. It repreſents the object erect, and peculiarly diſtinct; but its field of view is ſmall, in compariſon with the aſtronomical teleſcope of an equal magnifying power.

The common *opera glaſs* is nothing more than a very ſhort Galilean teleſcope. It magnifies little, but it ſhews the objects erect and much illumined; hence it is moſtly uſed in places wherein the objects are rather obſcure.

The *night* teleſcope is a ſhort teleſcope, of about two feet in length, and often ſhorter. It repreſents the objects inverted, but much illumined; though little magnified. Its field of view is very extenſive; hence it is uſed moſtly or entirely in the night time either by navigators or by aſtronomers; the former uſing it for diſcovering objects that are not very diſtant, but which cannot otherwiſe be diſcerned for want of ſufficient light, ſuch as veſſels, coaſts, rocks, &c.; and the latter for diſcovering comets, or other not very luminous objects.

Almoſt all theſe different teleſcopes are often conſtructed with an achromatic object lens; in which caſe the epithet *achromatic* is annexed to their peculiar appellations.

DIORDULI, in *Ancient Geography*, a people placed by Ptolemy in the eaſtern part of the iſland of Taprobana.

DIORPHUS, a mountain of Aſia, in Armenia, near the Araxes, according to Plutarch.

DIORTHOSIS, διορθωσις, in *Surgery*, an operation, by which crooked or diſtorted members are made even, and reſtored to their primitive and regular ſhape.

DIORYX, in *Ancient Geography*, a canton of Aſia, in Aſſyria, near the Tigris.

DIOSANTHUS, in *Botany*, Διος ανθος of Dioſcorides, book vi. chap. 6, is merely enumerated by him among the coronary or ornamental plants, without any deſcription, except its being without ſcent. Hence it does not very clearly appear why ſome commentators have ſuppoſed this flower to be the Carnation, or Clove Pink, though others may be more correct who take it for the Sweet William. Linnæus, however, has adopted the name, a little changed, for his genus; to which both theſe plants belong. See DIANTHUS.

DIOSCOREA, (ſo called by Plumier after the Greek botaniſt Pedacius Dioſcorides.) The Yam. Plum. Gen. 9. t. 26. Linn. Gen. 525. Schreb. 693. Mart. Mill. Dict. v. 2. Jeſſ. 42. Gærtn. t. 17. Claſs and order, *Dioecia Hexandria*. Nat. Ord. *Sarmentaceæ*, Linn. *Aſparagi*, Juſſ.

Gen. Ch. Barren fl. *Cal.* Perianth of one bell-ſhaped leaf, in ſix deep, oblong ſegments, ſpreading at their extremities; the three innermoſt ſmalleſt. *Cor.* none, except the calyx be taken for ſuch. *Stam.* Filaments ſix, awl-ſhaped, very ſhort, oppoſite to the ſegments of the calyx; anthers of two diſtant lobes. Fertile fl. *Cal.* as in the barren ones. *Cor.* none. *Piſt.* Germen minute, triangular, inferior; ſtyles three, undivided; ſtigmas ſimple. *Peric.* Capſule large, three-lobed, with three cells, and three heart-ſhaped, compreſſed valves. *Seeds* two in each cell, imbricated, roundiſh, with a membranous border.

Eſſ. Ch. Barren fl. Calyx in ſix deep ſegments. Corolla none. Fertile fl. Cal. in ſix deep ſegments. Cor. none. Styles three. Capſule inferior, three-lobed, and three-celled, compreſſed. Seeds two in each cell, bordered.

Obſ. The capſule is juſtly repreſented inferior in the Hortus Malabaricus, though Linnæus, Juſſieu, and Gærtner thought it ſuperior.

Of this genus about 20 ſpecies are more or leſs perfectly known, their ſynonyms being greatly confuſed. We are not at preſent furniſhed with materials to elucidate them, for the plants being not very diſſimular in appearance, nor remarkable for beauty, they have been but little attended to by collectors. Their *roots* are generally tuberous, perennial, eſculent when boiled. *Stems* annual, twining, weak. *Leaves* moſtly alternate, ſtalked, heart-ſhaped, entire, with numerous ſimple ribs. *Flowers* in ſimple or branched cluſters, ſmall, greeniſh-white. Tuberous buds, which become roots, are frequently produced on the ſtem above the inſertion of the foot-ſtalks. D. *ſativa*, Linn. Sp. Pl. 1463. Hort. Cliff. t. 28, is generally taken for the Yam, and is certainly cultivated as ſuch in the warmer parts of America. But Forſter, in his Plantæ Eſculentæ 56, ſays D. *alata*, Linn. Sp. Pl. 1462, is the moſt univerſally cultivated in both Eaſt and Weſt Indies, the equinoctial part of Africa, and in the iſlands of the South Sea, its roots being no leſs grateful than wholeſome, when either boiled or roaſted, and uſed as bread. This is the *Katsjil Kelengú* of Hort. Mal. v. 7. t. 38; and, according to Forſter, the different ſpecies of *Ubium* in Rumph. Herb. Amboin. v. 6. book 9. t. 120.

to 123, and 125, referred by Linnæus to his D. *oppoſitifolia*, belong to the *alata*. The ſame author informs us "the root is often three feet long, as thick as a man's thigh, and weighs 30lb. Its bark is black, the internal part white and glutinous, becoming farinaceous when dreſt. The juice, when recent, is acrid, cauſing itching in the ſkin. A favourite diſh in Otaheite is compoſed of this root, with pulp of the *Muſa*, or Plantain-fruit, and grated cocoa-nuts." D. *bulbifera*, Linn. Sp. Pl. 1463. Saliſb. Parad. t. 17. (Katu Katsjil; Hort. Mal. v. 7. 69. t. 36.) A native of ſhady woods in Malabar, is not mentioned by Rheede as an eſculent plant, but the boiled root, mixed with powder of China-root, is uſed as an application to cleanſe and heal ulcers.

DIOSCORIDES, Pedacius, or Pedanius, in *Biography*, a celebrated Greek phyſician and botaniſt of Anazarba in Cilicia, now Caramania, who lived, as it is generally thought, in the time of Nero. He is ſaid to have been originally a ſoldier, but he ſoon became eminent as a phyſician, and travelled much, both in Europe and Aſia, for the purpoſe of acquiring knowledge. He paid particular attention to the Materia Medica, and eſpecially to Botany, as ſubſervient to Medicine. His knowledge of plants has been reckoned ſuperior to that of any other ancient writer; but Theophraſtus muſt always be excepted as by far the more philoſophical botaniſt, and one by whoſe information Dioſcorides profited, as Pliny ſubſequently did by them both.

Dioſcorides has left us a treatiſe on the Materia Medica, in five books, of which the beginning of the ſecond ſpeaks of animal ſubſtances, the reſt entirely of plants; alſo two books on the compoſition and application of medicines, an eſſay on counter-poiſons, and another on venomous animals. The beſt edition of his works was publiſhed in one volume folio, at Lyons in 1598, in the original Greek, with a Latin verſion and notes by Saracenus, or Saracin, a phyſician of that place. Aldus, however, had already publiſhed a Greek edition of Dioſcorides in 1495, and a Latin one had appeared at Cologne in 1478. His commentators have been numerous, but the moſt celebrated and valuable of them all is Matthiolus, whoſe numerous editions, illuſtrated with wooden cuts, are, ſome or other of them, eſſential to every botanical library. The fineſt of theſe, on account of the large ſize of the figures, were publiſhed in folio by Valgriſius at Venice, in Italian in 1565, and in Latin in 1583 and 1604. Linnæus uſed a ſmaller Latin edition of 1570 by the ſame printer, with cuts of the ſize uſual in the works of Cluſius, Gerarde, &c. Dioſcorides deſcribes or mentions about 600 plants, but his deſcriptions are often ſo ſlight and ſuperficial, founded on ſuch uncertain or variable characters, and ſo devoid of technical or ſyſtematical principles, that his commentators had ample ſcope for conjecture, and their controverſies with each other were, as Haller obſerves, terminated only by deſpair of ſucceſs. So vague were their conjectures in many inſtances, that not only the extremities of Europe, but even America, was ranſacked to explain a Greek plant. This has been a fertile ſource of error. Some good botaniſts have taken a more ſure way of aſcertaining the plants of Dioſcorides and Theophraſtus, by ſeeking them in the countries where they were originally deſcribed. Among theſe travelling botaniſts, Tournefort and the late Dr. John Sibthorp, Profeſſor of Botany at Oxford, will ever ſtand pre-eminent. The latter has determined ſome of the moſt celebrated Greek medical plants, hitherto miſtaken or unknown, as the φου and ελλεβορος μελας of Dioſcorides, the former of which proves a hitherto unknown ſpecies of Valerian, *Valeriana Dioſcoridis*, Fl. Græc. t. 33, and the latter a new *Helleborus*, intermediate, as it were, between the *niger* and *viridis* of Linnæus. Even amongſt the ſhepherds of the preſent day, Dr. Sibthorp met with traditionary accounts of the virtues of ſome plants handed down from the ancients. A root of the απιος, *Euphorbia Apios*, Linn., being ſhewn to a Cretan peaſant, the Profeſſor was aſſured by him that the upper part was emetic, the lower purgative, exactly as Dioſcorides relates. Several manuſcripts of this author's works with figures are extant, which have often been cited by his commentators. Of theſe the moſt celebrated is in the Imperial library at Vienna, the figures of which were partly engraved in the reign of the empreſs Maria Thereſa, under the inſpection of Jacquin. Two impreſſions only of theſe plates, as far as we can learn, have ever been taken off, as the work was not proſecuted. Of theſe one was ſent to Linnæus, with notes by Jacquin, and is now in the hands of the writer of this account; the other was given, out of Profeſſor Jacquin's own library, to Dr. Sibthorp, to aſſiſt his enquiries in Greece, and remains at Oxford. The Linnæan copy conſiſts of 142 plates, in oblong quarto, in alphabetical order, beginning with the αριστολοχια μακρα, and ending with ευζωμον, a kind of wild rocket or radiſh. Nothing can be more rude than theſe figures, except thoſe of Cuba and Dorſtenius, and they ſcarcely afford any information that is not familiar to botaniſts verſed in the ſubject. Haller aſſerts, that perhaps a third part of the plants of Dioſcorides is ſtill unknown, and it is to be feared they will never be entirely determined. The enquiry, indeed, at preſent, is rather a matter of curioſity than of any conſiderable medical importance. The remarks of this great Swiſs botaniſt on the botany of the ancient Greeks, are too juſt and ſtriking to be omitted here. "That ingenious people," ſays he, "were not formed for the ſlow and patient contemplation of nature. They noticed the moſt prominent points of their ſubject, but neither entered into the number of the parts of plants, nor their dimenſions, nor did they accurately define their forms. They ſcarcely ſought for any thing but plants uſeful in medicine, or neceſſary for ſome economical purpoſes. Yet they were not altogether ignorant of the importance of generic diſtinctions, for Dioſcorides adverts to ſeveral ſpecies of *Geranium*, and ſeveral of *Ranunculus*. The Greeks have by no means exhauſted the vaſt treaſures of nature which they might have obtained if they had examined, with equal care, the frozen regions of the Olympus and the warm iſles of the Archipelago. We muſt therefore in juſtice allow, that the botanical learning of the people in queſtion is no more to be compared with that of modern Europe, than with the induſtry of the Chineſe, Japaneſe, or Hindus. It is proper, nevertheleſs, to read the Greek authors, as the reputed virtues of plants have deſcended from them to us, with but little variation." Dioſc. Op. Haller Bibl. Bot. S.

DIOSCORON, or Dioscurum, in *Ancient Geography*, an iſland placed by Pliny on the coaſt of Magna Græcia, over-againſt the promontory Pacinium.

DIOSCURIA, διοσκουρια, from Διος, *Jupiter*, and κουροι, *infants*, in *Antiquity*, a feſtival in honour of the Διοσκουροι, or Caſtor and Pollux, who were reputed to be the ſons of Jupiter. It was obſerved by the Cyrenæans, but more eſpecially by the Spartans, whoſe country was honoured by the birth of theſe heroes. The ſolemnity was full of mirth, being a time wherein they ſhared plentifully of the gifts of Bacchus, and diverted themſelves with ſports, of which wreſtling matches always made a part. Potter, Archæol. Græc. lib. ii. cap. 20. tom. i. p. 384.

DIOSCURIAS, in *Ancient Geography*, a town of Aſia, ſituated on the N.E. coaſt of the Euxine ſea, that is, in the territory of Colchis. It was anciently called *Æa*, and, in proceſs of time, *Sebaſtopolis*. It was eſtabliſhed, according to Arrian, by a colony of Mileſians. P. Mela ſays, that it was founded by Caſtor and Pollux, who made a voyage to

Colchis with Jaſon. It muſt have taken the name Sebaſtopolis, denoting the town of Auguſtus, under the emperor, A great part of the commerce of the Euxine ſea centered in this town. It is now in ruins, under the name of *Sebaſtopoli.*

DIOSCURIUM, a town of the Peloponneſus, in Phlaſia, according to Polybius.

DIOS-GYS, in *Geography*, a town of Hungary; 32 miles W. of Tokay.

DIOS-HIERON, or *Temple of Jupiter*, in *Ancient Geography*, a town of Aſia Minor, in Ionia, ſituated at a ſmall diſtance from the ſea, between Lebedus and Colophone. It was conſecrated to Jupiter.

DIOSMA, in *Botany*, (ſo named by Linnæus from δις, διος, *Jove*, and οσμη, *a ſmell*, on account of its "divine odour," which in the *Dioſma hirſuta* he compares to that of the ſtarry aniſe, or *Illicium aniſatum*; ſee Hort. Cliff. 71. Nothing, however, can leſs deſerve the epithet of divine than the ſcent of ſome ſpecies, which makes the favourite perfume of the Hottentots, and approaches to that of rue and others of the ſame natural order with this genus.) Linn. Gen. 108. Schreb. 148. Willd. Sp. Pl. v. 1. 1133. Juſſ. 298. Gærtn. t. 94. (Hartogia; Linn. Gen 108.) Claſs and order, *Pentandria Monogynia*. Nat. ord. *Multiſiliquæ*, Linn. though referred by him, *Hartogia* at leaſt, to his *Aggregatæ*, from whence he ſubſequently eraſed it. *Rutaceæ*. Juſſ. next to *Dictamnus*, though placed by that author in a ſeparate ſection, the natural order in queſtion being at the time not well underſtood.

Gen. Ch. *Cal.* Perianth in five deep, ovate, acute, permanent ſegments. *Cor.* Petals five, eliptic-oblong, bluntiſh, ſeſſile, ſlightly ſpreading. *Nectary* five ſcales crowning the germen. *Stam.* Filaments five, awl-ſhaped; anthers ſomewhat ovate, incumbent. *Piſt.* Germen ſuperior, turbinate, with three or five angles, crowned with the nectary; ſtyle ſimple, erect, the length of the ſtamens; ſtigma ſmall, obtuſe. *Peric.* Capſules three or five, connected by their inner edge, ovate, pointed, compreſſed; their ſummits ſpreading; opening at the upper margin. *Seeds* ſolitary, oblong, poliſhed, encloſed in an elaſtic *arillus* of two valves.

Eſſ. Ch. Petals five. Nectary five ſcales crowning the germen. Filaments ſimple. Capſules three or five, connected. Seeds in an elaſtic bivalve arillus.

Obſ. From this genus are now neceſſarily ſeparated the D. *uniflora* and *unicapſularis* of Linnæus, the former being an *Erioſtemon*, the latter an *Empleurum*; ſee theſe genera. Hence the polymorphous character of *Dioſma*, alluded to by Linnæus in his Syſtema Vegetabilium, is in a great meaſure obviated.

Willdenow defines 30 ſpecies of *Dioſma*, all natives of the Cape of Good Hope or the adjoining country, and all ſhrubs of a moderate ſize, much branched with ſimple leaves, moſtly entire, ſometimes elegantly crenate; their form awl-ſhaped or linear, rarely elliptical or heart-ſhaped. The whole plant always abounds with pellucid glandular dots, the ſeat of a ſtrong-ſcented eſſential oil. Some few have ciliated leaves and calyx, but the general habit is ſmooth. The flowers are white or reddiſh, commonly handſome, and ſometimes ſweet-ſcented.

Nine ſpecies are enumerated in the Hortus Kewenſis, but ſome others have been brought into the Engliſh gardens ſince that work appeared. D. *hirſuta* is one of the oldeſt ſpecies. D. *ſerratifolia*, Curt. Mag. v. 13. t. 456, is a new and elegant one, ſaid to come from New South Wales, which is not improbable, as that country produces more genera of this natural order than any hitherto examined. The ſhrub in queſtion is very near the *crenata* of Linnæus, which laſt, with D. *pulchella* and *ericoides*, are ſaid to be principally uſed by the Hottentots, and called by them Bucku. The leaves are dried and powdered, and when mixed with greaſe ſerve to anoint the bodies of thoſe people, whoſe odour proved as diſagreeable to profeſſor Thunberg, as our more refined European pomatums frequently are to thoſe not accuſtomed to them, eſpecially ſince more cleanly habits have brought them into diſuſe.

Diosma, in *Gardening*, comprehends plants of the low growing ſhrubby exotic kinds; of which the ſpecies moſtly cultivated are the oppoſite-leaved dioſma (D. *oppoſitifolia*); the hairy-leaved dioſma (D. *hirſuta*); the red-flowered dioſma (D. *rubra*); and the heath-like ſweet-ſcented dioſma (D. *ericoides.*)

Method of Culture.—Theſe are plants which are capable of being increaſed by planting out the cuttings of the young ſhoots in the ſpring or ſummer ſeaſons, in pots filled with good mould, plunging them in a moderate hot-bed. After the plants have ſtricken good roots, they ſhould be carefully taken up and placed out ſeparately in pots, proper watering and ſhade being afforded; and they afterwards require to be protected from the effects of bad weather in the green-houſe, and to have the management of other ſhrubby exotic plants of a ſimilar low ſhrubby growth.

The great beauty of the bloom, and the fragrant ſmell of many of theſe plants, particularly entitle them to places in collections of the ſhrub kind.

DIOS-OROS, or Jovis mons, in *Ancient Geography*, a mountain of Africa Propria. Ptol.

DIOS-PAGE, a town of Aſia, in Meſopotamia. Pliny.

DIOSPOLIS, a town of Aſia, in Syria. Pliny places it near the town of Laodicea, on the ſea; Strabo places it in Phrygia. It is the ſame town with Laodicea on the Lycus, and is called alſo Rhoas and Laodicea.—Alſo, a town of Upper Egypt, called *Dioſpolis-magna*, the ſame with *Thebes*; which ſee.—Alſo, an epiſcopal town of Egypt, in the ſecond Thebaid, diſtinguiſhed by the epithet *little*, or *Dioſpolis parva*. (See Girge.)—Alſo, a town of Egypt, in the Delta, near Mendes, according to Strabo, and placed by Suidas in the nome of Buſiris.—Alſo, a town of Aſia Minor, in Bithynia, on the coaſt of the Euxine ſea. Ptol.—Alſo, a town of Arabia, afterwards called *Berytos*. Steph. Byz.—Alſo, an epiſcopal town of Thrace.—Alſo, a town of Paleſtine, called *Lydda*; ſituated on an extenſive plain, reaching from E. to W. from the Mediterranean to the mountains of Judæa, ſeven or eight leagues, and much more from S. to N. It was three miles from the town of Ramleh. The Itinerary of Antonine places it 32 miles from Jeruſalem, and 36 miles from Cæſarea. This place is mentioned under the name of Lydda in the ſacred writings; and anciently formed part of the kingdom of Iſrael, or Samaria, according to the 1ſt book of the Maccabees, ch. ii. v. 34. Mention is made of this town in the hiſtory of Pompey's expedition in Judæa. It ſuffered much during the civil wars of the ſecond triumvirate: Caſſius, when he was in the Eaſt, expoſed its inhabitants to public ſale; but Marc Antony, by a decree, reſtored their liberty, and re-eſtabliſhed them in their country. Joſeph. Antiq. lxiv. c. 18. The town of Lydda was burnt by Ceſtius Gallus, A. D. 66, when he went at the head of a powerful army to the ſuccour of king Agrippa. Pliny reckons it among the prefectures of Judæa, and Ptolemy places it in the number of the towns of that country. When Paleſtine was divided into three provinces under the reign of Arcadius, the town of Dioſpolis continued under the metropolis of Cæſarea.

DIOSPONTUM, a place of Aſia, in the ſecond Armenia,

nia, lying to the weſt of the Euphrates and the ſouth of Melas.

DIOSPORON, in *Botany*, (from διϛ, διος, *Jupiter*, and σπορος, a *ſeed*,) has ſometimes been uſed as a name for the Gromwell, or *Lithoſpermum officinale*, otherwiſe called by old writers *Milium Solis*. Theſe ancient names probably allude to the brilliancy and beauty of the ſeed, as the Linnæan appellation expreſſes its ſtony hardneſs. Pliny ſays ſome call it *Dioſ-pyron*. See DIOSPYROS.

DIOSPYROS, (from διϛ, διος, *Jupiter*, and either πυρ, a *fire*, or *flame*, or elſe πυρος, *wheat*. The latter is the opinion of Linnæus, the former of ſome commentators on Theophraſtus. The application of either is, in the preſent caſe, unintelligible. We have often ſuſpected that the Italian botaniſts of the 16th century, who firſt applied this name to the preſent genus, underſtood it as a jumble of Greek and Latin, *pyrus*, a pear, being not very unſuitable to the fruit in queſtion) Date-plum, or Perſimon. Linn. Gen. 550. Schreb. 736. Juſſ. 156. Gærtn. t. 179. (Guaiacana; Tourn. t. 371.) Claſs and order, *Polygamia Dioecia*, or rather *Octandria Monogynia*. Nat. Ord. *Guaiacanæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, in four, ſometimes five or ſix, deep, obtuſe, permanent, and finally enlarged ſegments. *Cor.* of one petal, urceolate, larger than the calyx, four-cleft; its ſegments acute and ſpreading. *Stam.* Filaments eight, (in D. *virginiana*, 16 in two rows) awl ſhaped, ſhort, firmly fixed in the receptacle; anthers oblong, acute, in moſt flowers ineffectual. *Piſt.* Germen ſuperior, roundiſh; ſtyle one, divided half-way down into four parts, permanent, longer than the ſtamens; ſtigmas obtuſe, cloven. *Peric.* Berry large, globoſe, with eight cells, (or rather from ſix to twelve), ſeated on the enlarged ſpreading calyx. *Seeds* ſolitary, roundiſh, compreſſed, very hard. Male flowers on a ſeparate plant, with a ſmall, acute, upright *calyx*; a ſquare, urceolate, coriaceous *corolla*, whoſe ſegments are revolute; long, acute, twin *anthers*, the innermoſt ſmalleſt; and only the rudiment of a *germen*.

Eſſ. Ch. Calyx four-cleft. Corolla urceolate, four-cleft. Style four-cleft. Stamens eight or 16. Berry with eight ſeeds. Male flowers on a ſeparate plant.

Obſ. This genus is very nearly related to *Royena*, as M. Desfontaines has ſhewn, in the Annales du Muſéum national d'hiſtoire naturelle, *v.* 6. 445, who aſſerts the only difference to be that *Royena* has only four cells in the fruit, *Dioſpyros* from ſix to twelve; and that the calyx of the latter has ſometimes five or ſix diviſions. Gærtner, *v.* 2. 80. *t.* 94, had already noticed the Linnæan deſcription of the fruit of *Royena*, taken, as he ſays, from Commelin's Hortus, *v.* i. *t.* 96, to be erroneous, and that it is really a berry of four cells, clothed with the calyx, which ſplits irregularly.

The ſpecies of *Dioſpyros* are not very numerous. They are trees, with very hard wood, and the fruit, when perfectly ripe, is in moſt caſes eatable, being ſweet and glutinous. In an unripe ſtate it is powerfully aſtringent. The leaves are alternate, ſimple, generally undivided. Flowers inconſpicuous, yellowiſh.

D. *Lotus*. Linn. Sp. Pl. 1510. Pallas Roſs. v. i. p. 2. 20. t. 58. Mart Mill. Dict. v. 2. (Guaicum patavinum; Ger. em. 1495. f. 1, 2.) "Leaves pale on the under ſide." This grows wild in the ſouth-eaſt parts of Europe, and will bear our climate in the open air, but we have never ſeen the ripe fruit. In Italy it comes to tolerable perfection, but is not eſteemed, otherwiſe than as a remedy for diarrhœas. D. *virginiana*. Linn. Sp. Pl. 1510. Mill. Ic. t. 126. Mart. Mill. Dict. v. 2. (Piſhamin, or Virginia Plum; Park. Parad. t. 569. f. 6.) "Leaves both ſides of the ſame colour." A native of Virginia, which has long been in our gardens. The leaves are ſmaller and broader in proportion than thoſe of the preceding, and though, like them, paler beneath, much leſs remarkably ſo. The flowers alſo are ſmaller. D. *Ebenum*. Linn. Suppl. 440. (D. melanoxylon; Roxburgh Corom. v. i. 35. t. 46.) Leaves elliptic-oblong, ſmooth, coriaceous, reticulated with veins. Buds hairy.—Found in the vaſt woods of Ceylon by Koenig, who ſent it to Linnæus as the true Ebony. Dr. Roxburgh alſo ſpeaks of it as the well-known and valuable Ebony. "It is only the centre of large trees," ſays that faithful obſerver, "that is black and valuable, and the quantity found is more or leſs, according to the age of the tree. The outſide wood is white and ſoft, and either decays ſoon, or is deſtroyed by inſects, which leave the black untouched. The ripe fruit is eaten by the natives, but is aſtringent and not very palatable." We are certain of the above ſynonyms and therefore cannot account for the report of a confuſion of two ſpecies in Linnæus, which Retzius calls D. *Ebenum* and D. *Ebenaſter*; the latter being the *Ebenum* of Linnæus, the former the genuine Ebony. See Martyn's Miller, and Retzius's Obſ. Bot. faſc. 5. 31, who quotes Rottboll in the New Copenhagen Tranſactions.

Four other Eaſt Indian ſpecies are deſcribed and figured by Dr. Roxburgh, D. *ſylvatica*, t. 47. D. *montana*, t. 48, D. *chloroxylon*, t. 49. "The wood of this is yellowiſh, very hard and durable, and uſed by the natives of the Orixa mountains for various economical purpoſes. The fruit when ripe is eaten raw, and is very palatable:" and D. *cordifolia*, t. 50.

Loureiro deſcribes the true Ebony as a diſtinct genus by the name of EBENOXYLUM, which ſee. This is a native of Cochinchina.

DIOSPYROS, in *Gardening*, contains plants of the deciduous ſhrubby flowering exotic kind; of which the principal ſpecies cultivated are, the European date plum (*D. Lotus*), and the American date plum (*D. virginiana*). The firſt of which riſes with a tree-like ſtem to the height of ſix feet; the ſmaller branches ſpread a little, and are yellowiſh; the leaves oval-lanceolate, large, quite entire, paler underneath, ſomewhat hoary, with the veins ſomewhat hairy; the flowers are ſmall, reddiſh white, rotate; the fruit the ſize of a cherry, yellow when ripe, ſweet with aſtringency; and the plant is a native of Europe.

The latter ſort riſes here to the height of from fourteen to ſixteen feet, commonly dividing into many irregular trunks near the ground; the wood is very hard, but brittle and ſomewhat white; the branches are many, and grow ſlender to the end, covered with a very thin greeniſh bark; the leaves many, broad, green, without dent or notch on the edges; ſo like the former, that it ſeems at firſt to be the ſame; it has a dark brown bark on the branches, but on the twigs it is greyiſh; the fruit is in form and bigneſs like a date, very firm as that fruit, almoſt as ſweet, with a great, flat, thick, large kernel within. It is found in Virginia and Carolina, in America.

Method of Culture.—The manner of increaſing theſe plants is by ſowing the ſeeds in a warm ſituation in the open ground, in the ſpring; but it is better when done in pots or beds filled with good earth, and plunged into a moderate hot-bed, as they riſe more quickly, and advance with greater rapidity. When the plants have attained ſome growth, they ſhould be gradually expoſed to the open air until the autumn, when thoſe in the full ground ſhould be carefully protected from froſt by mats or other means, and thoſe in pots placed under a garden frame, on moderate heat, free air being admitted when the weather is mild. Early in the following ſpring they ſhould be removed, and planted out in a warm ſituation in the nurſery, at proper diſtances, to remain two or more years, when they will be fit to be finally put where

they are to remain. They have a good effect in the large clumps, borders, and other parts of ſhrubberies, being ſufficiently hardy when of proper growth to reſiſt the effects of froſt in this climate.

DIOS-SACRA, in *Ancient Geography*, a place of Aſia Minor, upon the Thracian Boſphorus, near and in the northern part of the promontory Caracion.

DIOS-SOTEROS PORTUS, a port of the ſea of Laconia, ſituated at the bottom of the port, in which is found *Epidaurus Limera*.

DIOSTETWI, in *Geography*, a town of Sileſia, in the province of Oels; three miles S.S.W. of Mittelwalden.

DIOU, a town of Perſia, in the province of Choraſan; 270 miles N. of Herat.

DIOXIA, διοξεια, in *Muſic*, a name ſometimes given by the ancients to the diapente.

DIP *of the Horizon*.. See DEPRESSION.

DIP, in *Mining*, or *pitch*, ſignifies the greateſt inclination of a ſtratum to the horizon; the direction of this is always at right angles to the courſe, ſtretch, drift or run, which is that direction in which a level line might be drawn upon the ſtratum. The prevailing dip of the ſtrata in England is towards the S.E., and conſequently they are level in a N.E. and S.W. direction, and it ſeems more than probable, that the ſtrata of the whole iſland did occupy that poſition before the rupture and denudation of parts of its ſurface: the quantity of this dip was, however, but ſmall, probably not more than 1 in 70 or 80.

DIPÆA, in *Ancient Geography*, a ſmall town of Arcadia, in that part called Mœnalia.

DIPHACA, in *Botany*, (from δις, *double*, and φακη, a *legume*.) Loureiro Cochinch. 453. Claſs and order. *Diadelphia Decandria* Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth five-cleft, gibbous, permanent; its ſegments acute, the lower one longeſt. *Cor.* Papilionaceous. Standard roundiſh, ſomewhat triangular, notched, aſcending; wings ovate, ſhorter than the ſtandard; keel of two petals, lunate, equal to the ſtandard, with long ſlender claws. *Stam.* Filaments 10, united in two parcels, five in each; anthers oblong, incumbent. *Piſt.* Germens two, oblong, compreſſed, ſtraight; ſtyle of each awl-ſhaped, longer than the ſtamens; ſtigmas thickiſh. *Peric.* Legumes two, compreſſed, ſtraight, pointed, jointed; the joints ovate, ſtriated, ſmooth, unequal in ſize. *Seeds* ovate, compreſſed.

Eſſ. Ch. Legumes two. Stamens in two equal ſets. D. *cochinchinenſis*. Lour. Cochinch. 454. (Solulus arbor, or Roraco; Rumph. Amb. book 5. 100. t. 128.) A tree eight feet high, cultivated in the gardens of China and Cochinchina, and called in the laſt-mentioned country *Kim phung*. Its *bark* is uneven, brown, without thorns. *Leaves* pinnate, of about ſeven pairs, with an odd one, the leaflets ovate, rather ſmall, ſmooth, nearly ſeſſile, oppoſite or alternate. *Flower-ſtalks* in pairs, axillary, ſingle-flowered. *Flowers* pale.

Such is Loureiro's account, who quotes *Hedyſarum Ecaſtaphyllum*, now *Pterocarpus Ecaſtaphyllum*. Linn. Syſt. Veg. ed. 14. 642, as a ſynonym. But the latter is a Jamaica plant, with large ſimple leaves, ſilky beneath. The eſſential character, as given above, is truly wonderful, if correct, but Rumphius deſcribes and figures ſingle legumes from each flower, according to the univerſal courſe of nature in this tribe, as far as we have any knowledge. His ſynonym, therefore, or more probably the deſcription of Loureiro, muſt be erroneous.

DIPHRI, in *Ancient Geography*, a town of Phœnicia, Steph. Byz.

DIPHRYGES, or DIPHRYX, in the *Ancient Pharmacy*, the ſcoria or calx of melted copper gathered in the furnace, when the metal was run out.

The word is formed from the Greek δις, *twice*, and φυγειν, *to roaſt*.

DIPHTHERA, διφθερα, among the *Ancients*, a garment made of ſkins, and worn only by ſhepherds and country labourers.

DIPHTHONG, διφθογγος, in *Grammar*, a double vowel, or the union, or mixture, of two vowels pronounced together, ſo as only to make one ſyllable; as (1) the Latin *ae*, or *æ*; *oe*, or *œ*; (2) the Greek αι, ει; (3) the Engliſh *ai*, *au*, &c. See VOWEL, and SYLLABLE.

The word is Greek, and is compounded of δις, *twice*, and φθογγος *ſound*.

Ae anſwers to *ai*, the proper; and *æ*, the improper diphthong of the Greeks; *e. g.* Αινειας, *Æneas*; σφαιρα, *ſphæra*, &c. And, on the contrary, the Romans, when they had occaſion to divide the *ae*, changed it into the Greek *ai*; *e. g.* *aulai*, for *aulæ*, &c.

Ai, by ſome, is made a Latin diphthong, as in *aio*, *Caius*, &c. But in *ais*, and *ait*, *i* manifeſtly belongs to the latter ſyllable; and the Greek write not γαιος, but γαιος; whence it ſeems plain that *ai*, in the Latin tongue, is not a diphthong, as in the Greek.

The Latins pronounced the two vowels in their diphthongs much as we do, with this exception, that the two were not heard equally, but the one was ſomewhat weaker than the other; though the diviſion was made with all the delicacy imaginable; among us moſt of the Latin diphthongs are loſt in the pronunciation; their *æ* and *œ* are only ſpoken as *e's*; ſo alſo the Engliſh *ea*, *oa*, &c. though wrote with two characters, are pronounced as ſimple ſounds.

In Engliſh French, and divers other languages, one may diſtinguiſh diphthongs with regard to the eye, from diphthongs with regard to the ear.

A diphthong with regard to the eye is formed of two vowels, meeting in the ſame ſyllable, whether the particular ſound of each of them be heard in the pronunciation, or whether the ſound of one of them be drowned; or, laſtly, whether a new ſound, different from either of them, reſult from both. In the two latter caſes, it is with ſome impropriety that we call them diphthongs: the firſt only are real diphthongs, as being ſuch both to the eye and ear.

Diphthongs, with regard to the ear, are either formed of two vowels, meeting in the ſame ſyllable, whoſe ſounds are ſeverally heard; or of three vowels in the ſame ſyllable, which only afford two ſounds in the pronunciation.

On this laſt occaſion, diphthongs, with regard to the ear, are triphthongs with regard to the eye.

Engliſh dipthhongs, with regard both to the eye and ear, called *proper* diphthongs, are *ai*, as in *fair*; *au*, in *laud*; *ee*, in *bleed*; *oi*, in *void*; *oo*, in *food*; and *ou*, in *houſe*.

Engliſh *improper* diphthongs, or diphthongs with regard to the eye, are *aa*, pronounced only like *a*, as in *Aaron*; *ea* like *a*, as in *ſwear*, *heart*, or like *e*, as *already*; or like *ee*, as *veal*; *eo*, like *e*, in *feoffee*; or like *o*, as in *George*; *eu*, or *ew*, like *u*, in *Deuteronomy*; *ie*, like *e*, as *cieling*, *field*; *ei*, like *a*, in *feign*; or like *e*, in *deceit*; *oa*, as in *cloak*, *doat*; *oe*, as in *doe*, *oeconomy*; *ue*, as in *gueſs*; and *ui*, as in *guile*, *recruit*.

DIPHYES, from δις, and φυειν, *to generate*, in *Natural Hiſtory*, a name given by ſome authors to a kind of ſtone, which repreſents both the male and female parts of generation of the human ſpecies; and owes its figures merely to the accidental conformation of the hinge and protuberances of a ſhell, in which it has been formed. We have a ſpecies of chama, whoſe external form at the mouth repreſents the

female pudenda; but the figure of the ſtone is owing to the internal ſhape of the ſhell in which it has been caſt. This is an unknown ſpecies of concha anomia, which has ſuch ridges in one ſhell, and ſuch cavities in the other, that the ſtone caſt or moulded in it, has on one ſide the figure of the female pudenda, and on the other the male: it is uſually of a duſky brown colour, and of a ferruginous ſubſtance. As the ſame ſhell may, however, have received in different places different ſubſtances into its cavity, all which would neceſſarily be of this form, we hear, among authors, of ſome black, and ſome white ſtones of this kind. Authors have treated of this ſtone in a very idle and fabulous manner; but this is its true hiſtory.

DIPHYLLEIA, in *Botany*, (from δις *double*, and φυλλον *a leaf*, "becauſe the plant is conſtantly furniſhed with two leaves," Michaux Boreali-Amer. v. 1. 203. Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Ranunculaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of three oval, concave, deciduous leaves. *Cor.* Petals ſix, larger than the calyx, ſpreading, oval, concave, deciduous. *Stam.* Filaments ſix, very ſhort, flat; anthers oblong, vertical, their cells joined by a membrane from top to bottom, by the ſeparation of which they open. *Piſt.* Germen ſuperior, ovate; ſtyle ſcarcely any; ſtigma capitate. *Peric.* Berry nearly globular, of one cell, ſeſſile. *Seeds* two or three, roundiſh.

Eſſ. Ch. Petals ſix. Calyx of three leaves, deciduous. Berry ſuperior, of one cell, with two or three ſeeds.

D. *cymoſa*. Michaux, t. 19, 20. Found by that botaniſt in the rivulets of the high mountains of North Carolina, flowering early in May. *Root* creeping, apparently perennial, jointed. The *herb* has the habit of *Podophyllum peltatum*. *Stem* ſimple, two feet high. *Leaves* two, alternate, ſtalked, kidney-ſhaped, ſomewhat peltate, two-lobed, jagged, toothed, veiny, ſmooth. *Cyme* terminal, many-flowered, erect. *Flowers* white. *Stamens* ſhorter than the petals, and oppoſite to them. *Berries* blueiſh-black, with purple ſeeds.—From the deſcription and figures of Michaux, who thinks this genus allied to his *Caulophyllum*, t. 21, the *Leontice thalictroides* of Linnæus. The latter however belongs to the natural order of *Berberides* in Juſſieu.

DIPHYSA, (δις *double*, and φυσα a *bladder*, from the two inflated appendages to the legume,) Jacq. Amer. 208. Schreb. 500. Willd. Sp. Pl. v. 3. 1130. Juſſ. 362. Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*. Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, bell-ſhaped, a little compreſſed, divided half-way down into five ſegments; the two uppermoſt roundiſh, obtuſe, flat, widely ſpreading; the two lateral ones ovate, acute, erect, flattiſh; the lowermoſt lanceolate, pointed, concave, erect, rather longer than the reſt. *Cor.* papilionaceous. Standard obovate-oblong, large, notched, flat, with a concave claw as long as the tube of the calyx, the whole ſo bent back that the ſtandard itſelf is parallel to the claw; wings two, oblong, obtuſe, flat, ſhorter than the ſtandard, ſpreading in front, cohering behind ſo as to look like another ſtandard, furniſhed with a ſmall appendage at their baſe, tapering down into a ſlender claw, and curved backward in a ſemi-circle; keel ſickle-ſhaped, pointed, compreſſed, ſhorter than the wings, furniſhed with an appendage on each ſide at the baſe, divided behind at the lower part, and tapering into two ſlender erect claws, curved backward in the upper part ſo as to become parallel to the claws. *Stam.* Filaments 10, diadelphous, nine in one ſet, with a ſingle one, the length of the keel, in which they are encloſed; anthers ovate, ſmall. *Piſt.* Germen linear, roundiſh, ſtalked, about the length of the keel; ſtyle capillary, deſcending, extending beyond the keel; ſtigma ſimple, acute. *Peric.* Legume linear, compreſſed almoſt flat, obtuſe, of one cell; accompanied on each ſide by a large, longitudinal, membranous, inflated bladder, cloſed all round, originating from the oppoſite ſutures on each ſide. *Seeds* ſeveral, oblong, obtuſe, compreſſed, furniſhed with a ſmall hook. *Jacq.*

Eſſ. Ch. Calyx five-cleft, unequal. Legume of one cell, with many ſeeds, compreſſed, accompanied by a large longitudinal bladder at each ſide.

D. *carthagenenſis*. Jacq. Amer. 208. t 181. f. 51. Mart. Mill. Dict. v. 2. Common every where in buſhy places about Carthagena in New Spain, eſpecially at the foot of a hill near the leper's hoſpital, bloſſoming in Auguſt and September. The inhabitants call it *Vivaſeca*.

Jacquin, from whom alone we have any knowledge of this plant, Linnæus having left it unnoticed, deſcribes it as a ſhrub about ten feet high, of no beauty, and without thorns. *Leaves* pinnate, with an odd one, ſmooth, about two inches long, on the younger branches. *Flower-ſtalks* axillary, ſlender, each bearing two or three yellow inodorous flowers, about the ſize of the common *Colutea fruteſcens*. The bladders of the fruit are very remarkable. The *legume* is ſcarcely two inches long, and remains ſome time on the tree, failing to pieces at length tranſverſely, each portion containing one yellowiſh ſeed.

DIPLASIASMUS, from διπλασιαζω, of διπλοος, *double*; in *Medicine*, a reduplication of diſeaſes.

Diplasiasmus is alſo uſed for two muſcles in the arm, which ſerve to turn it about.

DIPLAZIUM, in *Botany*, (from διπλαζω, *to be double*). Swartz Syn. Filicum 91. (Hemionitis; Smith Act. Taurin. v. 5. 410. t. 9. f. 1. Tracts 235. t. 1. f. 1. Claſs and order, *Cryptogamia Filices*. Nat. ord. *Filices*. Linn. Juſſ.

Gen. Ch. *Capſules* annulated, in diſperſed twin lines, which are either ſimple or branched, running parallel, and cloſe, to the veins on the back of the frond. Sometimes one line is continued further than its companion, and in ſome parts of the frond even entirely ſolitary lines may be found; but it is ſufficient for the generic character if there be twin lines any where. *Involucrums* likewiſe in pairs, each conſiſting of an uninterrupted membrane, originating from each ſide of the vein, and ſeparating at its oppoſite margin.

Eſſ. Ch. Fructification in ſcattered lines, each of them double, with a vein running between. Involucrums originating from the vein and each ſeparating outwards.

Obſ. This genus was very properly eſtabliſhed by Dr. Swartz as diſtinct from the original *Hemionitis* of Linnæus, which he having ſeen in its native freſh ſtate found to have no involucrum. See Hemionitis. Dr. Smith, not having had the ſame opportunities of examining the latter, conceived his ſpecimens might have loſt this part from age, and therefore not being able to depend on a negative character which it was impoſſible to prove, he conſidered the ſpecies with involucrums as the only ones in a perfect condition.

Dr. Swartz enumerates nine ſpecies of *Diplazium*. Good examples of the genus are, D. *plantagineum*, Sw. Syn. Fil. 91. t. 2. f. 4. (Aſplenium plantagineum; Linn. Sp. Pl 1537. Hemionitis plantaginea; Sm.) "Frond ſimple, ovato-lanceolate, crenate, ſomewhat ſerrated; with a ſquare ſtalk." Found by Browne in Jamaica. The *ſtalk* is ſimple, ſmooth, naked, ſquare, about a ſpan high. *Leaf* about the ſame length, ovato-lanceolate; rather acute, crenate approaching to ſerrate with a ſtrong mid-rib, and numerous alternate, forked, diſtinct veins, along which the lines of fructification run on each ſide.

D. *grandifolium*. Sw. Syn. Fil. 91. (Aſplenium grandifolium; Sw. Prod. 130.) "Frond pinnate; leaflets lanceolate, broad, ſomewhat ſerrated, angular at the baſe."

Native

Native of Jamaica. *Frond* two or three feet high. *Leaflets* alternate, pointed, unequally ſerrated and ſlightly jagged. *Veins* numerous. *Lines* of fructification neither branched at their baſe, nor confluent at their extremities. *Involucrum* dark brown, revolute. *Capſules* pale.

DIPLOCONION, in *Ancient Geography*, a place of the Thracian Boſphorus, to the S. W. of *Rhodiorum Portus*.

DIPLOE, in *Anatomy*, is the reticular texture connecting together the two tables of the ſkull; ſee CRANIUM.

DIPLOIS, διπλοις, in *Antiquity*, a double pallium, or cloak, worn chiefly by the Cynics.

DIPLOMA, (διπλωμα, a διπλεμαι, *duplicor*) was originally a letter or writing of a ſovereign conferring a title or dignity, or granting ſome immunity or privilege, or ſome land, to be held in fief. The oldeſt is that of the emperor Galba diſmiſſing ſome veteran ſoldiers. They were called Diploms, becauſe they uſed anciently to be written on waxed tables folded together.

As theſe Diploms ſerve to eſtabliſh the rights of ſome families, towns, churches, convents, and provinces, to eſtates, lands, commons, or to any particular rights, privileges, and immunities, it is of material importance to be acquainted with the rules by which their authenticity may be proved or diſproved. See DIPLOMATICS.

In a more enlarged ſenſe, the word Diploma is ſynonymous with document, and ſignifies any writing which records a particular important tranſaction in a ſolemn form.

Latterly the meaning of the word Diploma has been reſtricted to a letter or writing of an univerſity, conferring the degree or dignity of doctor.

DIPLOMA, in *Chemiſtry*, denotes a double veſſel. Thus when one veſſel is put into another; the ingredients in the firſt, and the fire under the laſt, the chemiſt calls it boiling in diplomate.

DIPLOMACY, in *French, la Diplomatie*, is the knowledge of the relations of independent ſtates to each other.

The treaties, conventions, agreements, or rather the documents which more particularly eſtabliſh the relative rights of nations, and the obligations to which they are reſpectively pledged, were formerly called diplomas.

A diploma, ſays Johnſon, is a letter or writing conferring ſome privilege; but in a more enlarged ſenſe, it is any writing which ſtipulates a right, confers a privilege, or records one particular important tranſaction in a ſolemn form; and the ſcience which leads to the diſcovery of the age, authenticity, import and value of ſuch writings, is called *Diplomatics* (which ſee.)

But the relations of independent ſtates to each other do not originally reſt upon expreſs ſtipulations only. There is a natural law which traces the rights to which nations are reſpectively entitled. (See LAW of *Nations*.) Yet as there is no ſuperior coërcive power to enforce the performance of the correſponding obligations, nations are induced to unite together by means of treaties which are to render them more ſecure in the enjoyment of their rights. See TREATIES *of Peace and of Commerce*.

The collection of the principal treaties on which the external relations of the independent ſtates of Europe have depended till the year 1801, or the peace of Amiens, is to be found in "Leibnitz's Corp. Jur. Diplomat. Corps Diplomatique du Droit des Gens." Amſterdam, 1731. 8 vol. fol. "Hiſtoire des Traités de Paix et autres Négociations des Puiſſances de l'Europe depuis la paix de Vervins juſqu'à celle de Nimégue." Amſterdam, 1725, 2 vol. fol. "Lord Liverpool's Collection of Treaties of Peace." 1785. "Wenk's Codex Juris Gentium recentiſſimi." Lipſiæ, 1788, 2 vol. 8vo. "Recueil des principaux Traités conclus par les Puiſſances de l'Europe depuis 1761, par M. de Martens' Goetting. 1791, 8vo. "G. F. Von Martens, Grundriſo einer Diplomatiſchen Geſchichte der Europæiſchen Staatshændel und Friedens ſchlüſſe bis zŭm Frieden zŭ Amiens." Hamburg, 8vo.

Unfortunately theſe conventions labour under the ſame difficulty with the law of nations itſelf. Nothing enſures their performance. Independent and powerful ſtates break their contracts at pleaſure. In vain does juſtice condemn ſuch infractions of ſolemn engagements; there is no legitimate ſuperior power to which ſhe can truſt her ſword for the puniſhment of the offenders. Neither has the continual reſidence of diplomatic agents, introduced by cardinal de Richelieu, been able to keep up more ſecurely the relations of amity between independent ſtates; and vainly have the nations of Europe endeavoured to confide the guarantee of their rights to a combination of a certain number of ſtates leagued againſt others of nearly ſimilar ſtrength.

It was at the beginning of the ſixteenth century that the reformation, which broke down the overgrown power of Auſtria, and eſtabliſhed the independence of Holland, gave the firſt hopes of ſuch a balance. Theſe hopes were invigorated by Sweden and Turkey, obtaining in the political ſyſtem of Europe an importance which they had not before enjoyed. The progreſſive growth of the Pruſſian monarchy, and the interference of Ruſſia in the concerns of Europe, were ſuppoſed to render the equipoiſe ſtill more perfect; and the creation of a Tranſatlantic republic, which leſſened the weight of Great Britain, was hailed as the only circumſtance that had been wanting to conſolidate the admired fabric of a connected ſyſtem, in which one part of the European commonwealth was to be balanced by the other. (See POWER, *Balance of*.)

In this ſtate of apparent ſecurity, the ſtudy of diplomacy was almoſt every where neglected. The maintaining of the accuſtomed relations of amity was conſidered as being ſo eaſy and ſo ſimple that a moderate ſhare of talents, a fine figure, and a noble birth, were ſufficient recommendations for the moſt important diplomatic functions. They were entruſted to men capable of foſtering intrigues with courtiers, kept miſtreſſes, and favourites, but utterly unacquainted with the true intereſts of nations in their external concerns. The temper of the ſupreme magiſtrate abſorbed their fawning attentions, whilſt the nature of the component parts of the people which he governed never attracted their regard; ſo great was their confidence in the taliſman of modern diplomacy.

But the chimera of an equilibrium, that was to prevent the recurrence of wars, or at leaſt to ſhorten their duration, ſuddenly vaniſhed at the very time when it was triumphantly ſpoken of as realized. The partition of Poland, the incoherent and impolitic coalitions againſt France during her revolutionary frenzy, and the feebleneſs and unpopularity of the governments againſt which the fury of the French was directed when they began to yield to the luſt of conqueſts, overturned the baſis on which the relations of amity between the European powers had fondly been conſidered as immoveably fixed.

Whether the order of things, which will emerge from the preſent chaos of European politics, will ſuffer the ſuperſtructure of the connections of independent ſtates to be raiſed anew on the ſame foundation, it is impoſſible to conjecture. The principle of all external relations remains in the mean time what it has been. Alliances muſt be courted with thoſe powers from which no injury is to be apprehended, and which yet are able to annoy that power, or thoſe ſtates, which,

which, from their geographical poſition and ſuperior force, are dreaded as natural enemies. See ALLIANCE.

As diplomacy is the knowledge of the actual relative rights of nations, it conſtitutes the baſis of the negociations, to which governments have recourſe, when ſuch alliances are to be formed, when new ſtipulations are to be entered into on points in which two or more independent ſtates are mutually concerned, or when diſputes about the non-performance of ſome obligations, or about the violation of ſome rights, are to be ſettled. Hence, the term diplomacy is frequently applied, in a more reſtricted practical ſenſe, to the conducting of ſuch negociations, and to that branch of politics which provides for the ſafety of the ſtate by means of friendly connections with other independent powers. In this laſt acceptation, it is better known by the appellation of *Foreign Politics*.

The management of foreign politics is generally delegated by the executive power to one, or, in ſome countries, to two miniſters of ſtate, called "Miniſters for Foreign Affairs." In France, it is entruſted to the "Miniſtre des Relations Extérieures;" in Spain, to the "Miniſter del Deſpatcho Univerſal;" in Great Britain, to the "Secretary of State for the Foreign Department," whoſe province it is to watch over both the political and commercial intereſts of the country abroad, and to appoint its diplomatic and commercial agents.

The functions of diplomatic agents, in general, are, to watch, in the ſtate to which they are ſent over, the intereſts of the ſtate which ſent them; to endeavour to obtain, by ſkilful negociations, the conceſſion of the points which they are inſtructed to ſolicit; to collect the moſt complete information about the ſtrength, energy, connections, and projects of the government of the country where they reſide; and to tranſmit regular diſpatches, on thoſe different ſubjects, to their own governments. See DISPATCHES.

As theſe reports, or diſpatches, contain, in general, communications of importance, they are moſtly written in cyphers, which, for greater ſecurity, muſt frequently be changed. See CIPHER.

The qualities moſt requiſite in a diplomatic agent are, political information, an active and enlightened mind, a correct judgment, a dignified firmneſs, conciliating manners, and an inviolable fidelity and diſcretion, which, however, muſt not exclude candour and openneſs. See NEGOCIATOR.

The aggregate of all the diplomatic agents of foreign powers, reſiding at one time in the ſame place for diplomatic purpoſes, is called the *Corps Diplomatique*, diplomatic body.

There are three claſſes of diplomatic agents. The firſt is that of ordinary and extraordinary ambaſſadors. (See EMBASSADOR.) They are ſent to thoſe powers with which the ſtate wiſhes to treat on a footing of equality, whether they be really of equal rank, or only conſidered as ſuch by courteſy. The ſecond is that of plenipotentiaries, or envoys. (See ENVOY and PLENIPOTENTIARY.) They differ from ambaſſadors with regard to their preſentation only; they do not go, nor are they received, in ſtate at their firſt audience.

The third claſs of diplomatic agents is, that of reſidents and chargés d'affaires. The latter are generally firſt ſecretaries of ambaſſadors, left to tranſact the buſineſs of their reſpective ſtates, during the temporary abſence of the ambaſſadors. Reſidents are permanent diplomatic agents in ſmall principalities, ſmall republics, or Hanſeatic cities. See RESIDENT.

The ſubaltern agents in diplomacy are the ſecretaries of legation, private ſecretaries of the ambaſſadors, and dragomans, or interpreters. See DRAGOMAN and SECRETARY.

Commercial agents are appointed to watch over the commercial intereſts of the ſtate in the country where they reſide, to aſſiſt the trading ſubjects of the government, by which they are appointed, in their dealings, according to the ſubſiſting treaties, and to communicate to their reſpective governments any commercial or political information which they conceive to be of importance. They are of two ſorts; general conſuls, in foreign places of extenſive trade, and vice conſuls appointed by the former in leſs important commercial places of the ſame diſtrict or country, and approved of by government. See CONSUL.

DIPLOMATICS, DIPLOMATICA, is the knowledge of the age, authenticity, preciſe import, and relative value of old documents, formerly called diplomas.

Documents, or diplomas, are writings which ſtipulate a right, confer an eſtate, a fief, a privilege, a title, or a dignity, or record one particular important tranſaction in a ſolemn form. The word diploma occurs but rarely in the documents themſelves. They are generally ſtyled "Præceptum, Auctoritas, Privilegium, Pagina, Charta, Littera, or Litteræ, Apex, or Apices, Pancharta, Sanctio Pragmatica, Inſtrumentum, Indiculus, Placitum, Notitia, Bulla, Sigillum, Sigillati Apices, &c." The ancients called them "Syngrapha, Chirographa, Codicilli." The originals are named "Exemplaria, or Autographa, Chartæ Authenticæ, Originalia;" and the copies "Apographa, Copiæ, Particulæ." The collections that have been made of them are denominated "Chartaria, and Chartulia," and the places where they uſed to be kept "Scrinia, Tabularium, Aerarium," and in Greek "Archeium, or Archivum."

Documents are almoſt as ancient as writing itſelf. Every civilized nation, the Hebrews, Phœnicians, Egyptians, Babylonians, Perſians, Greeks, and Romans, had documents which they preſerved in their archives, and which they conſulted for hiſtorical and juridical information. Yet none have been diſcovered of a date anterior to the 5th century. The ancients were accuſtomed to reduce their contracts and treaties into writing; but they engraved them on tables, or covered them over with wax, braſs, copper, ſtone, or wood, and all thoſe which were not traced on braſs or marble have periſhed by the length of deſtructive time.

Documents, or diplomas, were anciently written on metals and ſtones. Job exclaims, "Oh! that my words were now written! Oh! that they were printed in a book! that they were graven with an iron pen and lead in the rock!" Job xix. 23, 24; afterwards they were written on paper and parchment. The paper of the ancients came from Egypt, and was formed of thin leaves, or membranes, taken from the branches of a tree named Papyrus. Hence it was called "Papyrus, Biblum Ægyptiacum," or ſimply "Charta." (See PAPER, PARCHMENT.) The Papyrus, however, was never uſed in England; neither was it known in Germany nor in Hungary. The two latter countries invariably employed parchment in their diplomas till the 14th century, when the uſe of modern rag-paper was introduced, even on ſolemn occaſions, or for the recording of important tranſactions. In England, all documents or writings of importance are ſtill invariably written on parchment.

The uſe of ink in writing is very ancient. Baruch declared, that he wrote Jeremiah's prophecies with ink in the book. Jeremiah, xxxvi. 18. Black ink, as it is the oldeſt, was the moſt common. The ancients alſo wrote with red ink, made of vermilion, red-lead, or purple colour, "ſacrum encauſtum;" ſometimes in letters of gold, ſilver, and purple; and ſometimes with blue, green, or mixed ink, of a variegated hue.

For

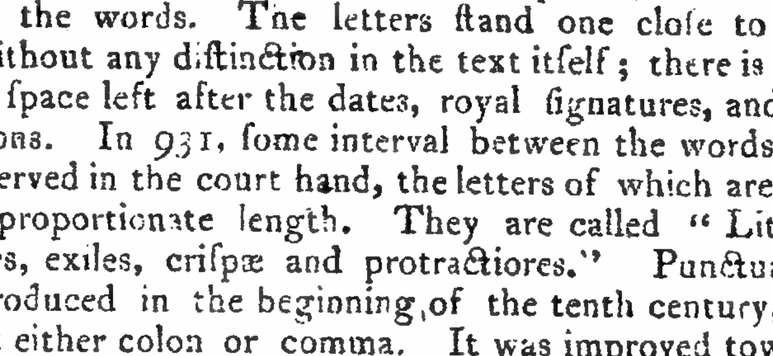
DIPLOMATICS.

For the invention of alphabetical writing, ſee LETTERS. With regard to the poſition of the lines, *verſus*, there were three ſorts of writings; the horizontal, from right to left, from left to right, or both ways, called βουστροφηδὸν; the perpendicular, from top to bottom, or from the bottom to the top, and both ways, either from right to left or from left to right; and the circular, *orbicularis ſcriptio*, as round ſeals, medals, &c.

In the oldeſt documents there are no points, no intervals between the words. The letters ſtand one cloſe to the other without any diſtinction in the text itſelf; there is only a ſmall ſpace left after the dates, royal ſignatures, and abbreviations. In 931, ſome interval between the words was firſt obſerved in the court hand, the letters of which are of a very diſproportionate length. They are called "Litteræ longiores, exiles, criſpæ and protractiores." Punctuation was introduced in the beginning of the tenth century, but without either colon or comma. It was improved towards the end of the twelfth and in the thirteenth century.

J. L. Walther, in his Lexicon Diplomaticum. Goettingæ. 1745. fol. which ſhould have properly been entitled Lexicon Abbreviaturarum, gives the beſt account of the abbreviations that have been uſed in different centuries.

The characters which are called "notæ, or notæ Tironis," Tiro's notes, are not to be found in any alphabet. They repreſent whole words. Their uſe is very ancient. They were invented to facilitate quick writing, and as ſuch they correſpond with the different characters of modern ſhort-hand writing. That ſuch characters were known to the Hebrews is inferred from king David's ſaying in the beginning of the 45th Pſalm: "My tongue is the pen of a ready writer." It is, however, certain that Xenophon was the firſt who uſed them among the Greeks, and that Cicero's amanuenſis, Tiro, from whom they derive their name, improved them into a perfect ſyſtem of ſhort-hand writing or tachygraphia. The following lines are a ſpecimen of Tiro's notes.



Lingua Mea Calamus

Seribæ Velociter Scribentis

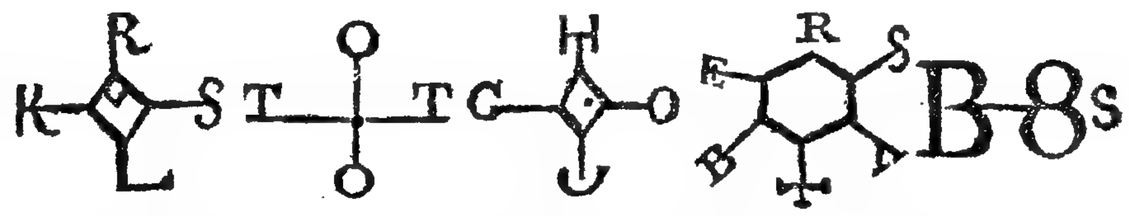
Conſult D. P. Carpentier's Alphabetum Tironianum. Paris, 1747. fol.

The knowledge of the different hand-writings of different ages and nations is beſt acquired in Henſelii Synopſis univerſæ Philologiæ; in Kapp's neu eröffnetem in hundert Sprachen beſtehendem A B C buch; in Mabillon De Re Diplomatica; and in the Nouveau Traité de Diplomatique. vol. ii. p. 479, and vol. iii. p. 687. In England, for inſtance, the old German hand prevailed from the fifth or ſixth century, till the year 1066, when William the Conqueror introduced the Capetian French writing. The new Gothic or black letter, ſuch as is ſtill uſed in the titles of ſome books, prevailed from the thirteenth to the ſixteenth century, when the old elegant Latin or Roman hand was reſtored and beautifully improved in Great Britain.

From the fifth to the thirteenth century the ſign of the croſs, called "Chriſmon, Chriſmum, Chriſmus, or Chriſmos," was uſed in ſignatures. In the ninth century the ſolemnity of the ſigning of documents was increaſed by the addition of the ſymbols of inveſtiture, as "per alapam, per amphoram plenam aquæ maris, per forfices," of which the following inſtance is recorded: "Odo Comes de Corboilo (Corbeil) conceſſit Deo et S. Germano Pontiſarienſi; quandam vieriam quam habebat in terra moriſſarti, deprecante matre ſua comitiſſa de Croceio, cum forficibus, quas in manu tenebat, cum quibus forficibus Robertus Monachus reinveſtivit eum de beneficio loci. Quibus etiam forficibus ſtatim idem comes totondit quendam armigerum Walteri Toſardi." Per oſculum, of which there is this inſtance: "Maino, filius Gualonis, annuente Eudone filio et vieta uxore ſua dedit Deo et S. Albino terram de Brilchiot pro cujus doni confirmatione Walterium Monachum pater et filius in fidei nomine oſculati ſunt. Uxor autem illius, eo quod a femina Monachum oſculari inuſitatum habemus, Lambertum quemdam Præfectum S. Albini, jubente Walterio Monacho, eadem ſententia deoſculata eſt." Per pileum. It was by the ſymbol of the hat that king Richard of England gave the emperor Henry VI., whoſe priſoner he was, the inveſtiture of his kingdom. Per virgam et pileum. The inveſtiture of duchies in England was generally given by the ſymbol of the rod and the hat.

The ſignatures frequently conſiſt of monograms or ciphers, (chifres,) compoſed of the letters or the initials of the names of thoſe who ſubſcribed the documents. The word monogramma is ſeldom mentioned in the text; but, inſtead of it, we find the following expreſſions, ſignum, *i. e.* crucis; "nominis or manus ſignum, manus propria, manus propriæ nota, chirographum, ſignaculum, character, character nominis, regius character, regii nominis character, ſigni character, nominis figura, &c." The firſt who uſed a monogram in the ſignature of a document was *Theodoric* king of the Oſtrogoths between the years 493 and 526. But it was Charlemagne, who rendered monograms faſhionable and introduced their conſtant uſe. Since pope Leo IX. or from the year 1050, almoſt all the bulls of the popes have two monograms, one before and the other after the ſignature of the pope's name. In Great Britain monograms have never been uſed.

The following are the monograms of Charlemagne, Otto the firſt, Hugo Capet, Robert of France, and Boſo king of Provence.



Seals, or ſignets have been uſed ever ſince the time of the patriarch Jacob. Geneſis xxxviii. 18. Exodus xxviii. 11. They were known to the Egyptians, Babylonians, Medes, Perſians, Greeks, and Romans. They are mentioned by the names of ſignum, till the 5th, 6th, and even the 14th century, "bulla, bulla cerea, ſignetum, ſignaculum, impreſſio, imago, imaginis impreſſio, imaginis ſignum ſecretum." But the moſt ancient name is annulus, (in diploms it is often ſpelt anulus,) which laſted until the tenth century, after which the word ſigillum is the moſt general. The Anglo-Saxons uſed ſeals, as appears from documents of the years 955 and 1066. Until the 8th century the affixing of a ſeal was abſolutely neceſſary to complete the ſolemnity of a tranſaction recorded in a document. From the 8th to the 12th century the uſe of ſeals was optional; the ſigns of the croſs and other ſolemnities frequently ſupplied their place. But from the 12th to the 15th century ſeals recovered their ancient

cient importance, and they have been conſtantly employed ſince that time by kings, princes, biſhops, abbots, noblemen and private gentlemen, ſo that no document was reputed valid unleſs properly ſealed; indeed the ſeal ſupplied the place of almoſt all the other formalities.

The ſeal was anciently of white wax imprinted on the parchment itſelf, ſigillum impreſſum. This method of ſealing was uſed in England until Edward the confeſſor and even William the conqueror, or the year 1087; in France until Louis le Gros or the year 1137; in Germany until Frederick I. or the year 1190. It was afterwards pendent from the document, and incloſed in a box or caſe, called *bulla*. The ſeal itſelf was then named *pendulum*. The oldeſt pendent wax ſeal is that of a document of Noricon biſhop of Laon in Picardy of the year 961. His cotemporary the Engliſh biſhop St. Dunſtan affixed his ſeal in the ſame manner, ſo that the pendent ſeals are of the ſame antiquity in England as in France. The kings of England uſed white wax until Charles I. Green wax is appropriated to the ſealing of charters. See SEAL.

Latin was the diplomatic language in both the eaſtern and weſtern empire until the year of our era 602, after which the Greek language alone was uſed in the documents of the eaſtern, and the Latin in thoſe of the weſtern empire. The Greek was alſo the diplomatic language of the kingdoms of Naples and Sicily during the 11th, 12th, and 13th centuries. In England the Latin and the native or vulgar language were uſed indifferently, the Anglo-Saxon from the 8th till the 13th century, except that from William the conqueror to Edward III. the French was the diplomatic language in public tranſactions; but private documents continued to be written in the Anglo-Saxon. The Latin was entirely diſcontinued and the Engliſh language alone employed after the year 1362.

Every document has a beginning (prologus), a text, (textus), and a concluſion (epilogus). The formulæ prologi were invocatio divina, nomen et titulus, promulgatio, exordium.

The invocations uſed under the firſt Carolingians were: "In nomine Dei et Salvatoris noſtri Jeſu Chriſti;" or "In nomine patris et filii et Spiritus Sancti." After Charles the Bald; "In nomine Sanctæ et individuæ Trinitatis;" and in a ſuppoſed document of Henry II. about the duchy of Benevent, of the year 1014; "In nomine domini Dei omnipotentis patris, filii et Spiritus Sancti," which affords an additional proof of the unauthenticity of this document. In the 13th century, the invocation was ſometimes omitted: but in the year 1512, the emperor Maximilian I. obliged the public notaries to uſe the invocatio divina in their inſtruments.

With regard to the name and title, the pronoun *ego* or *nos* was not prefixed to the names before the middle of the thirteenth century. Until the ſixteenth there never was but one Chriſtian name. Of the kings of the Saxon heptarchy in England, there was always one who was conſidered as the chief, or ſupreme monarch above the other ſix. Aetdibalt, in the year 730, is on that account ſtyled Rex Britanniæ, although he was only Rex Merciorum. The words Dei gratia were frequently expreſſed by "Divina clementia; divina favente clementia; divina concedente, auxiliante, juvante, opitulante, propitiante, diſponente, diſpenſante, miſeranda, præordinante clementia." The moſt common is divina favente clementia, which was introduced by Pepin.

The formula promulgationis was for inſtance; "Noverint omnes fideles noſtri tam præſentes quam futuri." Some documents are without an exordium. This generally expreſſed the motives of the tranſaction, which were derived "a pio, ab honeſto, ab utili, a decoro, &c.;" for inſtance: "Quia memoria hominum labilis eſt, et tempora prætereunt more fluentis aquæ."

In the text itſelf we may obſerve, that ever ſince Otto the Great, kings and emperors, in ſpeaking of themſelves, uſe the expreſſions "cellitudo, majeſtas, ſerenitas, regalis magnificentia, ſublimitas, regale culmen." The words cum conſilio principum, are not to be found before the tenth century, and the term feudum appears only in the time of the emperor Frederick. Till then it is always called beneficium.

The concluſion, or epilogus, contains the formula roborandi, as for inſtance: "Et ut hæc auctoritas noſtra firma ſtabiliſque permaneat, chartam hanc conſcribi juſſimus." It was ſometimes ſtrengthened by penalties or by maledictions, of which there are inſtances of the moſt ſhocking nature in J. G. Leuckfeld's Antiquitatibus Walkenredenſibus, p. 31, and in other collections of documents. It alſo mentions the witneſſes, the date of the tranſaction, when it was reſolved upon, which is called actum, and the votum finale; for inſtance; "in Dei nomine," or "in Dei nomine feliciter, amen," or "feliciter amen," or ſimply "feliciter." But this votum finale is frequently omitted.

Thus the different hand-writings of the different ages; the materials on, and with which the documents are written; their accentuation, punctuation, and abbreviations; their various ſignatures, marks, monograms, and ſeals; the language, ſtyle, and orthography of each age, as well as the different inchoative and final formulas, &c. conſtitute ſo many characters by which the authenticity of a diploma or document is to be aſcertained. When it bears all the marks which are requiſite for the time when and the place where it is ſuppoſed to be written, its authenticity is no longer to be doubted; but documents cannot be examined too minutely, becauſe the monks and prieſts of former ages have diſplayed uncommon ingenuity in making counterfeits. Their ſucceſs in theſe forgeries ceaſes, however, to aſtoniſh, when it is recollected that they enjoyed the confidence of princes and ſtateſmen, and were even ſometimes in poſſeſſion of their rings and ſeals.

With regard to manuſcripts or books written before the invention of printing, the art of judging of their antiquity and diſcerning their real authors, is a branch of literary criticiſm, and not of diplomatics. (See CRITICISM, MANUSCRIPT.)

The ſcience of diplomatics owes its origin to a Jeſuit of Antwerp, named Papebroch, who applied himſelf to the reſearch and expoſition of old diplomas, about the year 1675. His work is entitled "Propylæum." (See PAPEBROCH.) The Benedictine monk, John Mabillon, conſiderably improved this new ſcience in his learned work, "De Re Diplomatica," printed in 1681 (ſee MABILLON), which was unjuſtly and unſucceſsfully attacked in England by the celebrated Hickes, in his "Ling. veter. Septentr. Theſaurus. Præfatio," p. xxxv. The Italian Maffei's diplomatic hiſtory is but a ſupplement to Mabillon. But it is to Touſſaint and Taſſin, two Benedictine monks of St. Maur, that we are indebted for the largeſt work extant on diplomatics, entitled "Nouveau Traité de Diplomatique," Paris, 1750--1765. 6 vols. 4to. with plates. The founder of its practical ſtudy in Germany was John Heumann von Teutſchenbrunn. His "Commentar. de Re Diplom. Imper." was publiſhed in 4to. at Nurenberg in the year 1745. The "Dictionnaire raiſonné de Diplomatique," by Dom de Vaines, Paris, 1774, 2 vols. 8vo. is a compilation intended to aſſiſt beginners in the ſcience.

Diplomatics have been lately reduced to a complete ſyſ-

tematical ſcience by J. C. Gatterer, in his "Abriſs der Diplomatik," Goettingen, 1798, 8vo. and by C. T. G. Schoenemann, in his "Proluſio de finibus artis diplomaticæ practicæ regundis," and in his "Verſuch eines vollſtændigen Syſtems der allgemeinen beſonders æltern Diplomatik." Goettingen, 1802.

DIPLOPIA, in *Surgery*, is double viſion; from διπλοος, *double*, and ὄψις, *viſion*. (See the articles EYE, SIGHT, and VISION.) Perſons affected with this rare diſeaſe will perceive objects double, treble, or otherwiſe multiplied, when they look at them with both eyes; but they will generally ſee them ſingle, when viewed with only one eye. Sometimes, indeed, the objects may appear double when ſeen with one or both eyes. Commonly the patient ſees one of the ſpectra more diſtinct than the other; ſometimes, however, he ſees both equally diſtinct, ſo that he cannot aſcertain the real ſituation of the object by the ſenſe of ſight.

Double viſion is ſometimes temporary, and of ſhort duration; but ſometimes it is permanent, and even periodical. Sometimes the patient ſees double, only after he has exerted his eyes violently for a ſpace of time; ſometimes he ſees objects double only from one ſide or the other, either right or left; ſometimes alſo he ſees double, whichever way he may direct his eyes.

The cauſes of double viſion may be diſtinguiſhed into four claſſes. In the firſt, the object produces a double ſpectrum upon the retina; in the ſecond it forms a ſpectrum in one eye, which is different, with reſpect to apparent ſize, poſition, diſtance, diſtinctneſs, &c. from that which is formed in the other; in the third the ſpectrum is formed upon a part of one eye not correſpondent with that upon which it is formed in the other; or the ſenſation of the optic nerve is diſordered. When the diſeaſe ariſes from cauſes of the firſt and fourth claſs, the patient ſees double as well when he uſes a ſingle eye, as when he uſes both; but when it ariſes from cauſes of the ſecond and third claſs, he only ſees double when he uſes both eyes at once; and when he ſhuts the one, he ſees objects perfectly natural, that is, ſingle, with the other.

The principal cauſes of the firſt claſs are: 1ſt, an unevenneſs of the cornea, which is divided into two or more convex ſurfaces; 2d, an unevenneſs of the anterior ſurface of the cryſtalline lens, which is divided into ſeveral ſeparate ſurfaces; 3d, a double orifice in the iris, or a double pupil, as it is termed. Theſe cauſes are incurable. The cauſes of the ſecond claſs are, in general, ſuch as are rather poſſible, than that they have actually been obſerved. All the defects of viſion to be mentioned hereafter may ſometimes ariſe only in one eye; the refraction of the rays of light may be ſtronger in one eye than in the other; the patient may be in one eye *myops*, and in the other *preſbyops*; in conſequence of a peculiar defect of viſion, the patients ſee every ſtraight object as if it were crooked; all which defects may give riſe to double viſion. The third principal cauſe is ſquinting. In this diſeaſe the object is repreſented in both eyes in points not correſpondent with each other. But a perſon that ſquints does not ſee objects double, unleſs when he ſees equally diſtinct with both eyes, and the ſtrabiſmus does not ariſe from any weakneſs of either of the eyes, but from ſome other accidental cauſe. (See STRABISMUS.) This ſpecies of double viſion may be eaſily known by the patient's having begun to ſquint, and to ſee double at the ſame period of time. The cauſes of the fourth and moſt frequent claſs are the irritations which act upon the nerves of the eye, and modify their power of ſenſation in ſuch a manner, that objects which operate upon them are not repreſented in their natural form. Theſe irritations are of various kinds, and generally dependent upon the ſtate of the viſcera; they may, however, be produced by other irritating cauſes.

In the laſt ſpecies, the principal object muſt be to diſcover and remove the irritating cauſe. A boy, who became affected with double viſion in conſequence of a ſtroke which he received from the bough of a tree, was cured by the external uſe of infuſ. rad. valerian, with ſpir. vin. crocatus. A caſe of double viſion, produced by a violent fright, was cured by means of valerian, after cream of tartar had been uſed for three days previous to its adminiſtration; one ariſing from bilious obſtructions in the abdominal viſcera, was cured by pills of gum galbanum, guaiacum, rhubarb, and Venetian ſoap, combined with the uſe of emetics and purgatives.

When the irritation is of a tranſient nature, and after it has excited the diſeaſe, does not continue any longer to exiſt; or when the diſeaſe ſtill continues after the irritating cauſe has been removed, or finally when the irritating cauſe cannot be diſcovered and accurately determined, the ſurgeon muſt endeavour to remove the complaint by remedies that ſtrengthen the nerves and allay irritation. The following are particularly uſeful in theſe caſes: ſpir. ſal. ammon. dropped into the hand and held before the open eyes; ſpir. vin. crocat. externally; the warm eye-bath, eſpecially of capit. papav. alb. in decoction; the cold eye-bath; internally, Peruvian bark, valerian, ipecacuanha in ſmall doſes, Flor. zinci, and ol. cajeput. In one inſtance tart. ſolub. with fel tauri, and caſtoreum; in another, pulvis rhabarb., fel tauri, and aſa fœtida; and in a third, ſpirit. Mindereri with fel tauri, produced the moſt beneficial effects. In general, in all caſes, in which we cannot accurately determine the particular cauſe of the diſeaſe, we may ſuppoſe it to exiſt in the viſcera of the abdomen, and in ſuch caſes we may often do much good by the uſe of remedies that are gently purgative, and evacuant, and that allay irritation. See DELIRIUM.

DIPONDIUS. See DUPONDIUS.

DIPPEL's OIL, in *Chemiſtry*, ſo called from the inventor, Dippel, is the oil procured by the diſtillation of bones *per ſe*, and rectified by repeated diſtillations. The oil at firſt is extremely black, thick, tenacious, and fœtid. To rectify it, put it into a clean retort, taking care that none of it ſoils the neck of the veſſel in dropping it in. Then apply a moderate heat, by which a finer and clearer oil will riſe, and collect it in a clean receiver, ſtopping the proceſs as ſoon as it begins to drop foul and dark-coloured. This clearer oil is to be again diſtilled with the ſame precautions, taking only the firſt portion, and thus a perfectly limpid oil is obtained, the ſmell of which, though ſtrong and penetrating, is ſcarcely fœtid, and which is as fluid as water. It muſt be preſerved, however, in a dark place or an opaque bottle, for the action of the light renders it brown, fœtid, and nearly approaching to the ſtate of the oil from which it was obtained. Dippel's oil is a very powerful ſudorific in doſes of twenty or thirty drops, and it ſeems to deſerve more notice as a medicine than it has acquired, being now nearly diſuſed. See the article OIL.

DIPPER, in *Ornithology*. See COLUMBUS *minor*.

DIPPING, in *Calico-Printing*, a proceſs uſed in dyeing blue, in which the cloth is immerſed or dipped either in a ſolution of indigo, or of ſome ſubſtance capable of acting on indigo previouſly applied to the cloth.

The peculiar nature of indigo unfits it for the purpoſes of dyeing by the ordinary operations of the art. It conſiſts, as we ſhall have occaſion to ſhew more fully hereafter, of a peculiar vegetable baſis united to a portion of oxygen, to which it owes its colour and inſolubility. When deprived of this oxygen, by ſubſtances whoſe affinity for it are greater, it becomes ſoluble in the alkalies and alkaline earths, and in this

this ſtate readily contracts an union with animal or vegetable ſtuffs. On this property of the alkalies to diſſolve deoxygenated indigo, are founded two proceſſes for dipping or dyeing blue, which form the ſubject of the preſent article. The firſt conſiſts in immerſing the cloth in an alkaline ſolution of indigo, and is employed in dyeing thoſe goods, the ground of which is intended for blue or green. The parts meant to remain white, or which have already received ſome other colours, being covered with a reſerve or paſte, to protect them from the effect of the dye.

This proceſs is very ancient.

The ſecond is employed in dyeing thoſe goods intended to exhibit a deſign or pattern in one or more ſhades of blue, upon a white ground, and is called "China blue," or generally upon the continent, Engliſh blue, the proceſs having originated with the calico-printers of this country.

From time immemorial the nations of the eaſt appear to have poſſeſſed a mode of dyeing ſilk handkerchiefs, and other articles of dreſs, by a rude but ſimple proceſs, which is practiſed at this day, and has been adopted, and continues in uſe, in almoſt every part of Europe. It conſiſts in tying knots with great addreſs and nicety on the ſilk in ſuch a manner, that when dyed, the parts encloſed within the knot remain untouched, diſplaying a ground of red, blue, or any other colour, variouſly, and oftentimes not inelegantly diverſified with flowers of white or yellow, according to the primitive colour of the ſilk. This mode of dyeing handkerchiefs was introduced by the Saracens into Spain, where it is now practiſed to a very conſiderable extent. This, in all probability, was the firſt rude eſſay or attempt to imitate the printed linens of Egypt, and was ſucceeded by the mode now practiſed in India, of covering with a compoſition of wax and other ingredients, the parts intended to remain white. Hence we may date the origin of blue dipping, and though the proceſs, as may be ſuppoſed, has been conſiderably improved ſince its introduction into Europe, yet the ancient practice is ſtill in uſe; and wax printing is often employed with conſiderable advantage in the production of particular combinations of dark and light blue, which could not readily be obtained by any other proceſs.

Of the Indigo Vat, and the Proceſs of common blue Dipping.

The ſolution of indigo for blue dipping, is made in large oblong veſſels of wood, ſtone, or other materials, to which the name of vats is given. Thoſe which are made of wood require to be very accurately joined, and well ſecured with bolts and ſtraps of iron; otherwiſe great loſs may ariſe from the conſtant leakage, to which, without great precaution, they are ſubject. In general they are lined with lead, and though the expence in the firſt inſtance is four times that of wood, they are eventually much cheaper. They need fewer repairs, and afford abſolute ſecurity againſt all loſs by leakage, which, in a drug ſo coſtly as indigo, is a conſideration of great importance. Stone vats have been tried in ſome places. At Rouen, according to Berthollet, they are conſtructed of a kind of flint-ſtone, well ſecured both outſide and inſide with a fine cement: and Pileur d'Appligny mentions ſome he had ſeen compoſed of large ſtone ſlabs ſcrewed together at the corners, and the joints of which were covered with a kind of maſtic varniſh. Economy is the chief aim in all theſe various conſtructions, as it matters little what the vat is compoſed of, provided it will hold the dye; and thoſe, in fact, are the cheapeſt, whatever they have coſt, that ſuffer the leaſt to eſcape.

The ſize of the vat varies conſiderably in different dye-houſes, according to the nature and extent of the eſtabliſhment, and the kind of work they are intended for. Four feet wide, ſix feet long, and ſix or ſeven feet deep, are the dimenſions of a well-proportioned vat, calculated for two pieces of calico, or 56 yards of cloth on a frame. Much ſmaller than the ſize here given are in uſe for frames of ſingle pieces, and vats of ſtill larger dimenſions are employed by ſome, whoſe work and cloth require them one or two feet deeper.

The vats are all ſunk in the earth, down to a level, or nearly ſo, with the floor of the dye-houſe. In ſome few old eſtabliſhments, they ſtand two feet, or thereabouts, above the floor, as is univerſally the caſe on the continent. In this caſe, the frames are hoiſted in and out by a pulley ſuſpended over the vat, a moſt awkward and inconvenient practice, which is avoided by ſinking them to the level of the floor. The frames are lifted out with eaſe by the hand, by two men or boys, one at each end, and in a range of ſix or eight vats, the frames are hoiſted out and re-entered in half the time, and with half the trouble, required to manage the pullies.

The number of vats neceſſary in a well arranged dye-houſe muſt depend greatly on the nature and ſize of the eſtabliſhment. Eight of the ſize already given, ranged in one line ſide by ſide, form a good ſeries: double or treble that number may be required, but with fewer, a dyer, whoſe quantity of work is limited, yet various, will find much inconvenience, eſpecially when by long working the dregs or grounds have ſo accumulated as to require a repoſe of 24 hours at leaſt, after raking up before the vats are fit for work again. It is on this account that deep vats are preferable to ſhallow ones; the mud ſubſides in them much ſooner, and they require cleaning out and emptying leſs frequently.

The nature of the indigo vat is ſuch, that the indigo is revived and precipitated from it whenever it comes in contact with the air. On this account, it is impoſſible to dye a piece evenly by winching or working it in the dye liquor, as in other colours. Thoſe parts of the piece which had been moſt expoſed, and on which, of courſe, moſt indigo had been precipitated, would exhibit deeper ſhades than thoſe which had been leſs. The reſerve, or paſte, allo, for white, when ſuch had been applied, would be diſturbed and waſhed off by the uſual manipulations of dyeing.

On theſe accounts it is neceſſary to hook the pieces on a frame in ſuch a manner, that when immerſed in the vat, or taken out, the folds ſhall not touch each other. The frames are of wood, the length and width nearly of the vat, and of a depth ſufficient for the width of the goods. The horizontal ſide-rails at the bottom are fixed, and form the baſe of the frame, and are furniſhed with ſmall tenter hooks of copper an inch and a half, or two inches aſunder, to which the edge or ſelvedge of the piece is attached. The upper rails, which are alſo furniſhed with hooks, ſlide in a groove cut in the upright or corner poſts, and may be adjuſted to the width of any kind of cloth, and are retained in their place by a peg or pin. The piece is hooked in folds from ſide to ſide, and ſo evenly and tightly ſtretched, that when immerſed in the vat every part is equally and alike expoſed to the dye, and no one fold can touch another. The number of dips is regulated by the ſhade of blue required, and when finiſhed, the goods are taken off the hooks and ſubjected to the ordinary operations of waſhing, rinſing, &c. &c. The ſolution of indigo, which, as well as the veſſel that contains it, is generally called "blue vat" by the dyers, is made with lime and copperas, and in ſome caſes with the addition of a ſmall quantity of potaſh. In the due proportion of all the ingredients of this ſolution, and in the treatment of the vat, both during, and after working, conſiſt the chief art of "blue dipping," in the management of which, however, there is leſs difficulty than in any other branch of blue dyeing

whatever. The theory is ſo ſimple, and the practice, to thoſe acquainted with the theory, ſo very obvious, that with common care and obſervation it is ſcarcely poſſible to err.

Indigo, as we have juſt before obſerved, is inſoluble in the alkalies and alkaline earths, till deprived of its oxygen. Copperas is employed for this purpoſe in the vats we are ſpeaking of, and orpiment in others, and in the pencil blue; both theſe ſubſtances having a ſtronger affinity for oxygen than the baſe of the indigo. On adding together, therefore, indigo, copperas, and lime, in ſuitable proportions, the lime in the firſt inſtance decompoſes the copperas, and precipitates from it the oxyd of iron: this acts on the indigo, deoxygenates it, and renders it ſoluble in the lime, which, if in ſufficient quantity, immediately diſſolves it. The oxyd of iron, which has ſerved to deprive the indigo of its oxygen, the ſulphate of lime formed by the union of the lime with the acid of the copperas, and any lime in exceſs or more than neceſſary to effect the decompoſition of the copperas, and the ſolution of the deoxygenated indigo, all precipitate to the bottom of the vat, and there remains in ſolution only lime and the baſe of indigo. There are few dyers and calico-printers who do not imagine that the ſolution of indigo conſiſts of all the ſubſtances that have been uſed in its formation, and that the vat actually holds in ſolution indigo, copperas, and lime. They are not aware that ſolutions of theſe two latter ſubſtances are incompatible; they cannot exiſt together, one or other muſt predominate, as a very ſimple experiment will ſhew: Mix clear lime water, and copperas water together, and an inſtant precipitation will take place. As long as any copperas remains in ſolution, every ſucceſſive addition of lime water will cauſe a freſh precipitate, which conſiſts of oxyd of iron, and ſulphate of lime, formed by the union of the lime with the acid of the copperas. None of the lime remains in ſolution. The precipitation ceaſes only when the whole of the copperas is decompoſed, that is, when there is no longer any acid to form an inſoluble ſalt with the lime. The ſolution will then be found to conſiſt of lime water only. To thoſe in the leaſt acquainted with the principles of chemiſtry, theſe obſervations may appear minute and trifling, but to thoſe ignorant of theſe ſimple facts (and the majority of thoſe intereſted in the ſubject of the preſent article are ignorant of them,) the conſtitution of the blue vat muſt be wholly unknown, and its management, of courſe, expoſed to all thoſe chances of failure and derangement which muſt neceſſarily attend even long experience, when unaccompanied with clear and accurate ideas of the nature and properties of the different ſubſtances employed.

The proportions of indigo, copperas, and lime, neceſſary to form a blue vat, depend both on the quality of the indigo, and on the ſtrength of the ſolution required. The quality of indigo varies greatly, ſome kinds, as the fine Spaniſh and Eaſt India, containing twice, and even thrice, as much colouring matter as the coarſer kinds. In general from two to five pounds of good indigo to every hundred gallons of water, are ſufficient to form vats for moſt purpoſes. They are ſometimes, but rarely, required ſtronger; 40 pounds in a vat holding 800 gallons, will produce a ſolution of ſufficient intenſity to give a black nearly, at four or five immerſions.

The finer the quality of the indigo, and the greater the proportion of copperas and lime, neceſſary to effect its ſolution. In general, however, one of indigo, two of copperas, and two of lime, are conſidered as the beſt proportions, and as ſuch they are given by Berthollet, who, to profound chemical ſcience, unites conſiderable practical knowledge, and the beſt information concerning the proceſſes of the dyers and calico-printers of France.

The indigo is previouſly ground in a mill with water, till it is reduced to a ſmooth paſte of the conſiſtence of cream. In its ordinary ſtate of aggregation, it is ſcarcely, if at all, attacked by copperas and lime; all therefore that has eſcaped the action of the mill, and is put into the vat in a lumpy or imperfectly ground ſtate, may be conſidered as totally loſt. Every precaution therefore ſhould be employed to guard againſt this, and when by rubbing it between the fingers, or on a pane of glaſs, it appears fine and ſmooth, and free from ſmall hard, gritty particles, it may be removed from the mill, mixed up with four or five times its bulk of water, and poured through a fine ſieve into the vat. Any lumps which may have eſcaped grinding are thus retained, and may be returned into the mill with freſh indigo.

The vat having received its charge of indigo, and been filled up with clean water, the copperas is next added. It is beſt and moſt ſpeedily diſſolved by ſuſpending it in a wicker baſket at the ſurface of the vat; it is ſometimes thrown in, and will, in that caſe, when it is in large lumps, oftentimes lie undiſſolved at the bottom of the vat for weeks, in ſpite of frequent and even daily ſtirring. When the whole is diſſolved, the lime is added, and the vat well raked up, till all its contents are intimately mixed, the lime diſſolved, and the copperas decompoſed. The action of oxyd of iron upon indigo requires time, and alſo repoſe; after the firſt raking, which ſhould be continued during half an hour at leaſt, it is beſt to ſuffer the vat to remain two or three hours undiſturbed; the indigo and oxyd of iron fall down to the bottom, and are thus brought more within the ſphere of chemical action, than when floating in the whole maſs of water in the vat.

The choice of copperas is not a matter of indifference, as on its peculiar ſtate depends its fitneſs or not for deoxygenating indigo. Sulphate of iron exiſts in two ſtates dependent on the quantity of oxygen combined with its oxyd. At its minimum of oxydation, it forms a green ſolution, and when cryſtallized, a green ſalt, the green vitriol, or copperas of commerce; at its maximum, or ſecond ſtate of oxydation, it forms an orange-coloured, uncryſtallizable ſolution poſſeſſing very different properties from the former.

The green ſolution is diſtinguiſhed by its great avidity for oxygen, and its diſpoſition to paſs to the orange, or fully oxygenated ſtate. It is this affinity for oxygen that fits it for the ſolution of indigo. The copperas of commerce is however not unfrequently a mixture of the two ſalts or oxyds a portion of it either having acquired oxygen, whilſt in a ſtate of ſolution before cryſtallization, or more frequently perhaps by too great expoſure to the air afterwards.

In this latter caſe its ſurface is covered with a reddiſh orange ruſt, and a portion of the ſalt is rendered uſeleſs for the blue vat having already acquired its maximum of oxygen. The chief difference in the quality of copperas, is however in the more or leſs perfect ſaturation of the acid, forming two diſtinct ſalts, which were known and diſtinguiſhed by manufacturers long before chemiſts were acquainted with their exiſtence. The firſt, and leaſt eſteemed, is a pale emerald green, and contains a great exceſs of acid; the other, which is more fully ſaturated with iron, is a deep full green, and is univerſally preferred, eſpecially for indigo and China blue vats. Some calico-printers imagine that the reddiſh coloured copperas is the beſt, or, as they ſay, the *ſtrongeſt*, a prejudice which the manufacturer very eaſily accommodates, by ſprinkling a little fine ſifted quick lime over the ſurface, which ſoon covers it with a coat of orange ruſt.

The lime uſed for the indigo vat ſhould be quick. Fallen

lime,

lime, when not too old, and too long expoſed to the air, is the beſt. It ſhould be well ſifted, and freed from ſtones and lumps.

After two or three hours repoſe, the vat ſhould be again well raked. It will now exhibit ſigns of incipient ſolution; inſtead of black, it will appear of a dark bottle green, and the ſurface will break into marbled veins of blue. Theſe appearances will increaſe each time the vat is raked, which ſhould be three or four times a day during two days. At each time the colour of the vat will brighten, and get paler, the marbled or veined appearance become more marked and ſtrong, and when the ſolution is compleat, and ready for working, the colour, when raked up, will be a yellowiſh green. After a repoſe of ten or twelve hours, to allow the dregs time to ſubſide, the vat is ready for work.

It is the practice of ſome dyers to add potaſh in equal quantity with indigo to the vat. The only advantage ariſing from this, is greater concentration of the ſolution than can be obtained by lime alone; but this is ſeldom required, and never, indeed, for the purpoſes of calico-printing; on the other hand, if potaſh be added to a vat containing little indigo, and calculated only for the paler ſhades of blue, the colour it will produce is leſs intenſe, than when lime alone is uſed, and the hue not at all improved.

It was formerly the practice to grind the indigo with a ſolution of cauſtic potaſh, and boil it in a ſtrong lye, before adding lime and copperas, and pouring it into the vat. A great deal of trouble, and no advantage whatever attends this proceſs, which is now univerſally diſcarded, except by thoſe who regard all improvements as innovations.

Of the management of the vats both during work and after, we ſhall have occaſion to ſpeak whilſt treating of particular kinds of work; which, after the preceding general view of the nature of the proceſſes, and the mode of preparing the indigo vats, we ſhall now proceed to.

Of dark Blue ground, and white.

Dark blue grounds, with ſpots or figures of white, were amongſt the firſt attempts at calico-printing in the Eaſt, and were produced, as we have before remarked, firſt, by tying knots on the part intended to remain white, and afterwards by covering them with a compoſition of wax. This proceſs was ſubject to great inconveniencies, ariſing from the unmanageable nature of the compoſition, which required keeping fluid by heat during the time it was applied, and could only be uſed in certain plain figures, ſuch as round ſpots, ovals, &c. The deſigns were of courſe rude and ſimilar, little variety being practicable where lines, ſtalks, leaves, or any object more figured than a ſpot or oval, could not be obtained.

At what time the paſte or reſerve now in general uſe was introduced, is not known; we are indebted for it to the continent, from whence, indeed, our firſt knowledge of calico-printing was derived. Though the formulæ for this paſte differ much, every blue dyer almoſt, preparing it in a mode peculiar to himſelf, yet they are all eſſentially the ſame, a ſolution of copper of one kind or another being the principal ingredient.

If a ſolution of ſulphate, acetate, nitrate, or indeed any ſoluble ſalt of copper, properly thickened for printing, be applied to cloth, and when dry, immerſed in the blue vat, the part ſo covered will reſiſt the action of the dye, and remain white. This does not ariſe from the mere mechanical reſiſtance of the paſte, which prevents the ſolution of indigo from entering the fibres of the cloth, but from the chemical action of the oxyd of copper, which imparting oxygen to the indigo, reſtores it to its former blue ſtate, in which it poſſeſſes neither ſolubility in lime, nor diſpoſition to unite with the cloth. This effect of the oxyd of copper may be rendered very apparent, by pouring a ſolution of it into a ſolution of indigo, which is generally of a yellowiſh green, or when viewed by tranſmitted light, of the colour of ſmall beer. The inſtant the two ſolutions are mixed, the indigo is revived, and precipitated in its original blue ſtate, having acquired from the copper that principle of which it had been deprived by the ſolution of ſulphate of iron. Every paſte, or reſerve, therefore, for dark blue grounds, muſt neceſſarily contain oxyd of copper; we give the following formulæ as moſt approved of any in uſe.

I. To 1 gallon of water add,
4 lbs. of ſulphate of copper,
12 lbs. of pipe clay.

Boil the whole up into a thick paſte, ſtrain through a cloth, and add to it half a pint of ſulphuric acid, and five pints of thick gum water. Mix all well together, and ſtrain again before printing.

II. To 1 gallon of vinegar add,
1½ lbs. of verdigreaſe,
3 lbs. of ſulphate of copper.

Diſſolve them over the fire, and thicken with 12 lbs. of pipe clay, finely ground.

If the paſte is not fine and ſmooth, run it through the mill, and add to it, whilſt hot, 8 ozs. of linſeed oil, and two quarts of thick gum water. Strain it carefully through a cloth before printing.

III. To 1 gallon of water add,
2 lbs. of verdigreaſe,
3 lbs. of ſulphate of copper,
3 lbs. of nitrous acid,
15 lbs. of pipe clay.

Boil them well in a copper pan, and, if neceſſary, grind them ſmooth, and add three quarts of thick gum water. Strain the whole very well before printing.

The firſt of theſe formulæ contains ſulphate of copper only, the ſolubility of which is increaſed by the addition of a little ſulphuric acid, which prevents the cryſtallization of the paſte. The ſecond, which is ſtronger, contains alſo acetate of copper, and the third, in addition to both theſe ſalts, contains a portion of nitrate of copper formed by the action of the nitrous acid on the verdigreaſe. This is a very powerful paſte, and capable of reſiſting the vat a long time, and forming a white upon a ground nearly black.

The pipe clay uſed in thickening, is not merely uſeful in giving due conſiſtence and body to the paſte, ſo as to render it eaſily workable, but is very efficacious in reſiſting the dye; the ſame ſolution, thickened with gum only, will ſcarcely bear three immerſions, but with the allowance of pipe clay here directed, will ſtand ten or twelve. No more gum, indeed, ſhould be added than is juſt ſufficient to break the adheſive nature of the pipe clay, and prevent it clogging up the print or block.

In working this paſte the mall, or mallet, ſhould be uſed very lightly, or not at all, if the pattern will admit of it. A gentle tap with the hand, ſo as to leave the paſte wholly on the ſurface of the cloth, will produce the beſt work.

The cloth may be dipped an hour or two after printing, if required, but the whites are ſeldom ſo good as when kept three or four days. The paſte gets hard and firm, part of the acid evaporates, and the ſolution of copper becomes more intimately incorporated with the cloth.

Dark blues, in general, require from five to ten dips, or immerſions, according to the ſhade of blue required, or the ſtrength of the vats employed.

If the vats are ſtrong, five, or at moſt ſix dips, will give a very

very dark blue, almoſt black, the intenſity of which will be little increaſed by further dipping; the labour is greatly abridged by employing ſtrong vats, but the whites are liable to great injury, as the ſolution of indigo, when concentrated, acts very powerfully on the paſte. On this account the firſt vat ſhould invariably be the weakeſt of the ſeries, and never ſtronger than is ſufficient to produce a full ſtrong blue at ſeven, or even eight immerſions. The ſecond and third vats may be ſtronger, and ſo on to the laſt, which may be the ſtrongeſt of all. Dark blues may be dipped and finiſhed in the ſame vat, but it is more convenient to paſs them in ſucceſſion through a ſeries diſpoſed in a line in the manner we have before deſcribed.

When the piece is well hooked, and the frame ready, the vat muſt be well ſkimmed before the piece is entered. The ſurface of a blue vat is always covered with a film of revived indigo, more or leſs thick, according to the ſtrength of the vat. This film it is neceſſary to remove before the frame is immerſed, otherwiſe the revived indigo, which is no longer in ſolution, attaches itſelf, and adheres to the cloth in patches, producing unevenneſs in the dye, eſpecially in the firſt vat. When ſkimmed, the ſurface of the vat is dark green, but the blue film re-appears in a few minutes; it ſhould not be removed, therefore, till the frame is ready for immerſion.

In five or ſix minutes the cloth has fully imbibed the dye, and little advantage is gained in general by keeping it longer in the vat. The frame is then lifted out, and placed ſlantwiſe in ſuch a manner, that all the liquor which drains from the piece falls down into the vat again. When taken out, the cloth appears of a pale yellowiſh green, if the vat is weak, but if ſtrong, more inclining to amber. This colour gradually changes, as the indigo, by abſorbing oxygen from the atmoſphere, becomes revived, and in five minutes the cloth appears uniformly blue; it is then ready for another immerſion. Six minutes *in*, and ſix minutes *out*, is a good general rule for dipping dark blues, as the cloth will in that time have acquired the full effect of the vat, and *the green will alſo go off* in little more than five minutes, though the vat be very ſtrong. The bottom edge of the piece retains the green hue the longeſt, becauſe it is longeſt in draining from the liquor; care muſt be taken, therefore, never to immerſe a piece till the bottom edge has been examined, and found perfectly ready for the dip. The conſequence of entering a piece into the vat whilſt the bottom edge is green, is, as might be ſuppoſed, that the edge will be the paleſt, the indigo not having been revived and precipitated upon it equally with the reſt of the piece.

In dipping dark blues, the firſt dip is the moſt important; and if it fails, the work is inevitably ruined. Firſt, if the vat be too ſtrong, the whites will never be clear and ſharp; ſecondly, if for want of due preparation the cloth does not uniformly receive the dye, the goods will ſcarcely ever be even when finiſhed. Thirdly, if either from the paſte being too ſtrong, or the vat too weak, or not in proper order, the impreſſion ſtarts, or runs at the firſt immerſion, the ground is ſure to be freckled and uneven, and the whites bad.

Againſt the firſt ſource of error, the knowledge of the fact ought to be a ſufficient guard; but if unavoidably it ſhould happen that the leading vat is too ſtrong, there is no other remedy than ſhortening the time of the dip, and keeping the frame in four or five minutes in lieu of ſix, till the vat becomes reduced in ſtrength.

Imperfect bleaching, accidental impurity in the cloth, and long and partial expoſure to heat and air, are amongſt the cauſes which contribute moſt to prevent the cloth from receiving the blue dye.

It is the practice with many printers to give the cloth intended for this purpoſe an extra preparation, either by boiling in a lye of potaſh, or a ſolution of common ſalt. If the regular bleaching has been perfect, the firſt is wholly unneceſſary, and the ſecond abſolutely uſeleſs.

Cloth that has been well bleached may, by long keeping, and partial expoſure to the air, duſt, and other accidental impurities, become ſo unfit for dipping, as to require ſome extra preparation. In this caſe the modes we have ſpoken of may be uſeful inaſmuch as waſhing, ſoaking in hot water, ſqueezing, and the other attendant operations are uſeful, but clean, well bleached, and recently bleached cloth has no need of any ſuch preparation.

If the paſte be too ſtrong, that is, if it contains too much ſulphate, acetate, or nitrate of copper, it is liable to ſtart or run in the firſt vat, eſpecially when laid on in large bodies. This evil, if not too great, may be remedied by gently moving the frame up and down during the firſt two or three minutes after it is entered. It may alſo ariſe from the vat being too weak, and conſequently containing too little lime in ſolution, and may ſometimes be remedied by the addition of more lime. If in ſpite, however, of the motion of the frame, the addition of more lime, or of greater ſtrength to the vat, the paſte ſtill continues to run, it is a ſign the ſolution of copper is too ſtrong, and the quantity muſt immediately be diminiſhed.

When the green is gone off after the firſt dip, the frame is then moved on, and dipped in the ſecond vat, taking care to ſkim it well before the piece is entered. In this way, after each immerſion, the frame is moved on to the next ſucceeding vat, till it has received the number of dips required. This, as we have before obſerved, depends on the ſtrength of the vat, and the ſhade of blue wanted; but as, during the proceſs of dipping, the vats continually get weaker, the goods, after a certain time, will require an additional immerſion, or even two or three, to get them up to the ſtrength of the firſt pieces that were entered.

The ſtrength of a blue vat is not exhauſted in the ſame manner as the weld or madder bath, by the abſtraction of the colouring matter from the ſolution, by the ſuperior affinity of the mordant on the ſtuff. When a piece of cloth is immerſed in the indigo vat, it becomes penetrated in five or ſix minutes compleatly with the dye, and will gain nothing, by being ſuffered to remain longer than is neceſſary for this purpoſe. When taken out, it carries with it no more indigo than is contained in that quantity of ſolution which it has imbibed, and carries out of the vat. But the inſtant the frame is lifted out, the liquor begins to drain from it back again into the vat, and pours down in ſmall ſtreams, thus expoſing the ſolution compleatly to the atmoſpheric air. The indigo is in conſequence revived and precipitated, ſo that the liquor which drains from the piece, and falls down into the vat, is for the purpoſe of dyeing, no better than ſo much water. Every frame that is entered thus effecting the precipitation of the colouring from matter two, three, or four gallons of the ſolution, the vat, eſpecially the leading one, ſoon becomes reduced in ſtrength. The ſecond, third, and ſucceſſive vats, are weakened in the ſame manner, and alſo by the exhauſted liquor of the pieces, which at every dip after the firſt, is exchanged, as it were, for the freſh and ſtrong ſolution of the vat it is immerſed in.

When the goods have received the laſt dip, and have acquired their full ſhade of colour, they are taken off the hooks, and well winched in clean water; they are then, by the ſucceſſive operations of waſhing and hot watering, repeated as occaſion may require, freed from the paſte, and rendered as clean as poſſible before going into the ſours.

Souring is neceſſary to free them from the laſt remains of the paſte, and give a brightneſs and finiſh to the whites. A ſolution of ſulphuric acid, weak enough to be borne in the mouth without inconvenience, is ſufficient to diſſolve what oxyd of copper is left in the cloth after good cleaning. The goods are immerſed in this ten or fifteen minutes, after which they are well waſhed and hot watered, and when dry are finiſhed, or ready for any ſucceeding operations. The excellence of this kind of work depends on the clearneſs and purity of the white, and on the fulneſs and evenneſs of the blue. The directions we have given are, with ordinary care and obſervation, ſufficient for the attainment of this.

When the vats have become exhauſted by working, they muſt be *refreſhed*. If a vat contains a tolerable charge of indigo, copperas, and lime, and has been worked only once, raking up alone will be ſufficient to put it in a ſtate for working again. When again exhauſted, copperas and lime muſt be added to diſſolve the revived indigo. The quantity muſt depend upon the ſize of the vat, and the ſuppoſed quantity of indigo which it contains. From 20 to 40 lbs. of copperas, and three-fourths of that quantity of quick lime, may be added at once to a vat of 1000 gallons, or thereabouts, and ſome idea may be formed of the effect which this ſhould produce, by recollecting that one pound of indigo requires for ſolution about two pounds of ſulphate of iron. It is proper always to have an exceſs of quick lime in the vat, but it is wholly unneceſſary to make thoſe frequent additions of lime without any thing elſe, which is the practice of many blue dyers. It ſerves no other purpoſe than to fill the vat ſpeedily with dregs, which ought to be avoided as much as poſſible, as when they are accumulated to a certain pitch, it is neceſſary either to take them out, or ſuffer the vat to repoſe from 36 to 48 hours before it is fit for work after raking.

If equal quantities of copperas and lime have been uſed when the vat was formed at firſt, and three parts lime added for every four of copperas afterwards, any other addition of lime is wholly uſeleſs. Some idea may be formed of the ſtate and condition of a vat, by obſerving its appearance when raked up. In general, if it looks dark green or black, it may be preſumed it contains a quantity of revived or undiſſolved indigo, and copperas and lime are therefore neceſſary; this blackiſh appearance may nevertheleſs be occaſioned by a very great exceſs of copperas, or ſulphate of iron, the oxyd of which, when recently precipitated by lime, is dark green; as this, however, could ariſe only through great ignorance, or accident, it is not often likely to be the caſe, as the quantity of copperas required to produce this effect muſt be very great indeed.

When a vat rakes up yellow, or very pale yellowiſh green, it is ſuppoſed by ſome to contain too much copperas, and muſt be corrected by the addition of more lime. It is hardly correct, as we have before obſerved, to ſay a vat contains an exceſs of copperas, ſince this ſalt cannot exiſt in ſolution with lime. A vat may want lime, and in this caſe it will be very weak, of a pale yellowiſh green, produce a very feeble blue, and the paſte will invariably *creep*, to uſe the dyers' phraſe, or in other words, will run, and loſe the ſharpneſs and ſmartneſs of the impreſſion, the moment it is entered in the vat. This may be the caſe at the time the vat contains a quantity of revived indigo alſo, and rakes up black, ſo that no certain concluſion can be drawn from the yellowiſh appearance aforeſaid.

If a vat be weak, the froth which forms at the top during raking, is pale ſky blue; the ſurface does not ſpeedily break into marble veins, nor is it ſoon covered with a blue film. A ſtrong well conditioned vat, on the contrary, when raked up, becomes covered directly with a permanent and copious froth, the colour of which varies from a deep blue, when the vat is of ordinary ſtrength, to a bright copper colour, which is always characteriſtic of a very ſtrong ſolution, and the ſurface, when ſkimmed, is in an inſtant covered with a thick film of revived indigo. This film, and the deep blue and copper coloured froth, is the beſt and pureſt of the indigo, and is called the *flower of the indigo* by the old dyers. In ſkimming, great care muſt be taken that this is carefully preſerved, and returned again into the vats at the time they are refreſhed.

When a vat becomes ſo exhauſted that further additions of lime and copperas have no effect in increaſing the ſtrength, freſh indigo muſt be added, with the proportions of lime and copperas before indicated.

If a vat remains ſeveral weeks unworked and without raking, it will abſorb oxygen enough from the air to precipitate the indigo from the ſolution, ſo that, to the depth of 10 or 12 inches from the ſurface, it will conſiſt of lime-water only, and muſt be well raked up before it is worked.

When the dregs have accumulated ſo much as to prevent the vat from clearing in 24, or at moſt 36 hours, and when the frame begins to touch the mud during work, it is time then to empty it out, taking care to doſe the vat well with lime and copperas, ſo as to get out all the indigo before the dregs are thrown away as exhauſted.

Of Pale Blue.

Pale blues are, in general, produced at a ſingle dip; they require leſs indigo and labour than the preceding ſtyle of work, but more care and management to do them well. They are liable to be uneven and ſpotted in the ground, and the proper tone and ſhade of colour is a matter of great importance, and alſo of no ſmall difficulty.

We ſhall ſpeak firſt of pale blues and white, intended to be finiſhed up with after-colours or not.—The paſte for pale blue is preciſely ſimilar to that for the dark blue we have been treating of, except that it need not be ſo ſtrong. Two pounds of ſulphate of copper, diſſolved in a gallon of water, and thickened with pipe-clay and gum, in the manner of the three paſtes we have already given, will form a very good reſerve for pale blue. Any other ſolution of copper will be equally efficacious, but the ſulphate, as being the cheapeſt, may be conſidered as the beſt.

The preparation, or rather the condition of the cloth, is a matter of the greateſt importance in pale blue dipping. If imperfectly bleached, or ſtained or impregnated with any earthy or metallic ſubſtance that will obſtruct the entrance of the dye, the blue will infallibly be uneven. A difference in the quality of the cotton, in the fineneſs of the weft, or in the hardneſs of the twiſt, of which the cloth is made, will occaſion conſiderable variation in the ſhade of blue, and defeat every attempt, on the part of the workman, to do juſtice to his work. To guard as much as poſſible againſt this, the cloth, in the firſt place, ſhould be ſelected purpoſely, rejecting all thoſe pieces which ſhew unevenneſs in weaving, or variation in the quality of the materials.

The goods ſhould be in the beſt poſſible ſtate for printing; freſh from the bleach-ground, carefully kept from duſt or dirt of any kind, and ſufficiently damp to make them take a ſtiff calendering. As ſoon after printing as convenient, they ſhould be removed from the warm ſhop to a cool ſituation, where they will not get parched and dry, and dipped at furtheſt the following day.

All theſe precautions, however, are inadequate to ſecure an even and level ground, without recourſe to the improved

method of dipping, for which we are indebted to the calico-printers of London.

This improvement, whether conſidered with reference to the particular ſtyle of work, of which we are now treating, or its application to other branches of blue dyeing, the moſt important that has lately been introduced, conſiſts in dipping the goods in clear lime-water before they are entered in the blue vat.

If the piece becomes uniformly wet throughout, and ſhews no ſtreaks or patches of white, it may ſafely be transferred to the blue vat as a piece that will take an even dye. If, however, after remaining five or ſix minutes in the lime-vat, there are parts which are not compleatly wet, it muſt be dipped five or ſix minutes longer, and again taken out and examined. All thoſe pieces which, after two, or, at moſt, three immerſions, ſtill refuſe admiſſion to the lime-water, are rejected as unfit for dipping, and the paſte being removed by ſouring, are appropriated to ſome other courſe of work to which they are better adapted.

The vat for pale blues is, in general, the ſame as for the dark grounds, care being taken to ſelect one that will give the ſhade of blue required. It is uſual to employ the old and nearly exhauſted vats for this purpoſe, but the blue is never ſo bright and lively as when freſh indigo, and that of the fineſt quality, is employed.

The hue is greatly improved by ſouring, a neceſſary operation, to free the goods from the paſte, and ſtill further, by winching them in a ſolution of white ſoap 10 or 15 minutes, at a heat of 120°.

Mr. Hauſman obſerves, that if the goods are plunged in a weak ſolution of ſulphuric acid immediately on coming out of the vat, the blue is more lively and full than when previouſly rinſed and waſhed.

Mr. Chaptal employs for pale blue grounds without white, and for green grounds alſo, a vat compoſed of indigo, potaſh, lime, and orpiment. This ſolution, which is the ſame preciſely as the pencil-blue of the calico-printers, affords a much more delicate colour than that with lime and copperas, the cauſe of which is not clearly underſtood, though it moſt probably ariſes from the different degrees of deoxydation produced by the two ſubſtances.

This vat is formed by boiling 10lbs. of fine Spaniſh indigo, 10lbs. of potaſh, 20lbs. of quick-lime, and 5lbs. of orange orpiment, in about 30 gallons of water, and pouring it, when the ſolution is compleat, into the vat containing about 800 gallons of water, and 20 or 30lbs. of lime. When worked, it muſt be raked up well the inſtant before the frame is entered, and when exhauſted, refreſhed with additions of the ſame ſolution.

If a piece of cloth, printed with the reſerve or paſte before deſcribed, be dipped in this vat, the copper becomes precipitated and fixed by the ſulphuretted hydrogen which it contains, and produces a brown ſtain inſtead of a white. It is poſſible, however, with extraordinary care and management, to ſucceed in obtaining good whites in this vat, and the following proceſs may be employed with ſucceſs, though it is ſtill capable of further improvement.

Prepare a paſte by diſſolving 2lbs. of ſulphate of copper in one gallon of acetate of alumine, or the common aluminous mordant of the calico-printers, add to it 1lb. of nitrous acid, and 8lbs. of pipe-clay; boil well and ſtrain it through a fine cloth, and when cold, add as much thick gum-water as is barely neceſſary to give it the due degree of conſiſtence for working. In printing this paſte the mallet ſhould never be uſed, a gentle tap with the hand, if the block is true and in good order, will leave the paſte, as it ſhould be, wholly on the ſurface of the cloth. Dip ſix or eight minutes in the lime-vat, and when taken out, ſuffer the piece to drain two or three minutes before entering in the blue vat. The vat ſhould be ſtrong enough to produce the ſhade required in two minutes, after which the frame ſhould be withdrawn and plunged inſtantly in a vat of clear water, and moved and agitated therein till the green goes off. When waſhed and ſoured, if the work has ſucceeded, the white will be clear and prominent, and the blue the fineſt that can be produced on cloth. It is remarkable, that a ſtrong vat produces better whites than a weak one, on this account care muſt be taken, that the ſolution be of a proper ſtrength. The utmoſt nicety is required in preſerving the cloth for this vat from duſt or dirt of any kind. Goods that have been long bleached, and not carefully ſecluded from the air, are wholly unfit. They ought, in fact, to be taken freſh from the ſours, for every, even the ſmalleſt particle of metallic ſubſtance that is in the cloth, when dipped in this vat, will produce a brown ſtain, and if the cloth is uniformly tainted with it, entirely ruin the blue.

In dipping pale blue grounds, it is ſometimes neceſſary to protect colours that have been previouſly applied, from the effect of the blue, as red or yellow flowers for example, which would otherwiſe become purple and green. The ſolutions of copper cannot be employed for this purpoſe, as they injure the colours, eſpecially madder reds, or purples, very much, and are not wholly removed without ſouring, an operation which goods of this deſcription cannot be ſubjected to.

The reſerve moſt commonly uſed, is ſimply a paſte of pipe-clay or Spaniſh white, boiled to a proper conſiſtence, and mixed with an equal quantity of thick gum-water. This does not affect the colours upon which it is applied, and is eaſily removed by hot water and waſhing; but as it oppoſes merely a mechanical reſiſtance to the dye, and fails the moment it becomes ſoftened, it will not bear a dip of more than one minute or two. This is an inconvenience of great magnitude, when the pale blue ground is much expoſed, and not covered with any kind of deſign calculated to hide unevenneſs in the dye. The following paſte is recommended and uſed, by ſome, as capable of reſiſting much longer than the former:—

One pound of finely ground pipe-clay,
Four ounces of gum-arabic,
Two ounces of ſuet,
Two ounces of wax, and
One ounce of reſin.

Boil all theſe ingredients together, in as much water as will form a paſte of ſufficient conſiſtence not to run. This paſte can only be applied with the pencil, and in large maſſes. It is removed with great eaſe by hot water and waſhing, without any injury to the reds, or other colours it has covered.

The ſolutions of lead poſſeſs the property, though in a much ſmaller degree than copper, of reſiſting the indigo vat, and may be uſed with advantage for paſting reds and other colours, which are but little injured by them. We have ſeen the following paſte uſed with great ſucceſs:—

Diſſolve two pounds of acetate of lead in a gallon of water, add two ounces of tallow, two of wax, and two of reſin, and as much pipe-clay and gum as will make it of a proper thickneſs for printing or pencilling. This paſte will reſiſt a dip of three or four minutes; it muſt, however, be laid on in good bodies, and ſucceeds better with the pencil than block.

In pale blue grounds, with black and white figures, &c. it is often neceſſary to print both the black and the paſte

at

at the ſame time, to ſave the expence and trouble of after-grounding. The black for this purpoſe is generally chemical black, for an account of which we muſt refer to the article COLOUR-*making*. The ſulphate of copper paſte is generally uſed, but as the goods cannot, on account of the black, be paſſed through the ſours to free them from the oxyd of copper, which imparts a greeniſh hue to the white, it is better to employ the nitrate of copper, which is cleared by hot watering and waſhing much more compleatly.

If the patterns contain very large maſſes or bodies of black, the acetate of iron, or what the printers call black colour, muſt be uſed, increaſing the ſtrength to double that required for an ordinary black; ſo that when the goods are dipped, and as well cleaned as poſſible, by repeated waſhing, &c. they may be paſſed through water rendered ſlightly acidulous with nitrous, or what is ſtill better, acetous acid, without materially impairing the ſtrength of the mordant.

The white is compleatly freed from the oxyd of copper by this ſlight ſouring, and takes no ſtain in the dye copper, when the black is raiſed with ſumac and logwood.

It is proper to obſerve, that the goods, before ſouring, ſhould be compleatly freed from all ſuperfluous paſte, either of the black or white; and the iron, by repeated hot watering, at a temperature of 140°, oxygenated as highly as poſſible. In this ſtate it is ſcarcely ſoluble, either in nitrous or acetous acids, and will bear weak ſolutions of them 15 or 20 minutes.

Of Reſiſting Mordants.

When a pale blue is intended to exhibit other colours on the ground, as red, pink, yellow, orange, &c. the paſte or reſerve is often mixed with a mordant capable of producing theſe colours in the dye copper.

The common paſte alone will produce a yellow with weld, quercitron bark, fuſtic, &c. if the piece be ſimply rinſed and waſhed before dyeing.

In this caſe the oxyd of copper which remains in the cloth attracts the colouring matter, and though it is greatly inferior as a mordant, to the acetate of alumine, yet, with care and management, it is capable of producing, with weld, a pale and beautiful yellow. The only difficulty conſiſts in getting the colour even, and this is beſt attained by employing thoſe ſolutions of copper which are moſt ſoluble, and uſing them ſomewhat ſtronger than is merely neceſſary to reſiſt the vat.

When dipped, the goods ſhould be well rinſed in the river 15 or 20 minutes, and afterwards rinſed off in a copper of warm water, with a ſhovel full of cow-dung. Too much dung, or too great heat, will injure the yellow, the temperature ſhould not exceed 100°, and after winching again in the river, they ſhould be dyed at a heat conſiderably below this, if weld is uſed, and not exceeding 75 or 80 if dyed with bark.

Oxyd of copper, when dyed at a high temperature, invariably becomes dull, eſpecially when bark or ſumac are employed. With weld there is leſs riſk of injuring the brightneſs of the yellow, but long continued heat impairs it greatly.

This mordant does not at all anſwer for reds; with madder it affords a dull wine-coloured dye, and with brazil, peachwood, and cochineal, dull, heavy colours, more inclining to pompadour or chocolate than red. When mixed, even in ſmall proportions, with the common aluminous mordant, its effects are very viſible, when dyed with any of the above-mentioned drugs.

It is nevertheleſs employed for deep full reds, upon pale blue ground, according to the following formula, which is excellent for a yellow or orange:—

Diſſolve 2 lbs. of acetate of lead, and 2½ lbs. of alum, in a gallon of water; pour off the ſolution from the precipitate, and add 8 ozs. of ſulphate of copper; thicken with 1½ lb. of ſtarch, and 4 lbs. of fine pipe-clay. When cool, ſtrain the paſte through a cloth or ſieve, and give the goods ſix days age before dipping. Dip three minutes in a well-conditioned vat, and transfer the frame from thence inſtantly to the water-vat.—Rinſe off, and prepare for dyeing in the ſame manner as before directed.

The following formula is in uſe for reſiſting reds or yellows:—Diſſolve in one gallon of warm water 3½ lbs. of acetate of lead, and 5 lbs. of alum; thicken it (with the precipitate in) with the beſt Senegal gum, and add 2 ozs. of white arſenic, ground as fine as flour; 4 ozs. of common ſalt, and 4 ozs. of corroſive ſublimate. Give the goods two or three days age before dipping, and keep them from three to five minutes in a good vat, or leſs, if you can get the ſhade of blue required. Plunge them in the water-vat the inſtant they are taken up, and rinſe and finiſh as before.

Bark or weld drabs and olives, as they do not ſo ſoon ſhew any ſlight tinge of blue which may have penetrated the paſte, may be ſimply thickened with good ſtarch, and from 12 to 16 ozs. of ſuet per gallon, to enable them the better to reſiſt the vat. If this ſhould not ſuffice, from 2 to 4 ozs. of ſulphate of copper may be added, but it muſt be obſerved, that this will change the hue of the drab, and make it more an olive. A little pipe-clay, not more than 2 lbs. per gallon, may be employed alſo with advantage. It is very efficacious in keeping out the dye, and, in ſo ſmall a quantity, will not materially affect the fullneſs and evenneſs of the mordant.

Solutions of tin, more eſpecially the nitro-muriatic, are employed by ſome calico-printers, in conjunction with the aluminous mordant, for reſiſting reds and yellows. They are not very powerful in keeping out the blue, and, with madder, afford but feeble colours: the yellow they produce is bright, but pale.

In general, thoſe ſolutions which are moſt efficacious in reſiſting the vat, are the worſt mordants, as thoſe of copper for example; but as they will bear a long dip, and the evenneſs of the blue is thereby enſured, this advantage, in one colour, is conſidered as ſufficient compenſation for want of brilliancy in the other. The common aluminous mordant, thickened with gum and a little pipe-clay, or with ſtarch and pipe-clay, forms infinitely the beſt mordant, and will reſiſt the vat a few ſeconds, but not ſufficiently long to make the work ſecure. The recent improvement in this kind of dipping, however, by the uſe of warm vats, has removed a great many difficulties, and enabled ſome calico-printers to produce work of very ſuperior merit.

The great and the only advantage attending warm vats, is the celerity with which the dye penetrates the cloth; ſo that all the effect of a ſix minutes' dip in a cold vat, may, in a warm one, be obtained in the ſame number of ſeconds. The frame, in fact, is plunged in only for a moment, and inſtantly taken up; and, in this ſhort ſpace, the vat, however ſtrong, has not time to penetrate the paſte or mordant.

The vats may be variouſly heated, as beſt ſuits the nature of the eſtabliſhment. Steam affords the moſt eaſy and efficacious means, and may either be thrown into the vat through a pipe and valves, in which caſe the ſteam itſelf is condenſed in, and mingles with the ſolution of indigo, or the vat may be in part ſurrounded with a caſing, into which the ſteam may be admitted, and give out its heat, without filling the vat with condenſed water.

The firſt is the ſimpleſt and moſt economical mode; but it requires certain precautions which the other does not. In the firſt place, before the ſteam is admitted into it, the boiler ſhould be *blown*, that is, compleatly emptied of air; for if it paſſes along with the ſteam into a vat, the indigo will be revived, and precipitated from the ſolution, and the vat rendered unfit for dipping. In the ſecond place, if the vat, when cold, is only of the proper ſtrength, the admiſſion of ſo much ſteam, and conſequently of condenſed water, as will be neceſſary to raiſe it to the temperature required, will weaken it conſiderably; and laſtly, ſome inconvenience may ariſe from this great accumulation of condenſed water, unleſs due allowance be made before it is admitted, and care be taken never to turn it in when the vat is full.

The ſecond mode is ſubject to none of theſe inconveniences. The vat can neither be weakened by air from the boiler, nor by condenſed water, ſince the heat is tranſmitted wholly through the caſing. The expence, however, is very conſiderable; ſtill it is greatly preferable to the plan which ſome printers have adopted, of conſtructing caſt iron vats, and heating them by furnaces built underneath.

The temperature at which they can be employed, varies according to the kind of work, and the power which the paſte poſſeſſes of reſiſting a hot vat.

From 60 to 80° will be ſufficient for moſt purpoſes, and a vat of tolerable ſtrength will, at the latter temperature, produce a good blue in ten or fifteen ſeconds.

Of coloured Paſte.

By mixing both colouring matter and mordant with the reſerve, we obtain paſtes which at the ſame time communicate colour to the cloth, and reſiſt the blue; not only ſaving the neceſſity of dyeing, but enabling us to form combinations of colours, incompatible by any other proceſs. This branch of blue dipping is ſtill in its infancy, and little has yet been done towards its perfection. We ſhall therefore have little elſe to do in treating of this part of our ſubject, but to ſtate the few facts on which it is founded, and ſuggeſt ſome hints for its future improvement.

If a ſolution of ſulphate or acetate of iron be mixed with the reſerve or paſte for white, it will, when dipped and rinſed off, leave a buff or orange ſtain, not very ſtrong, indeed, nor always very even; but applicable and uſeful in ſome caſes. This paſte has been long known and employed.

If inſtead of acetate of iron a ſtrong decoction of bark, or French or Turkey berries, be mixed with the reſerve, a yellow will be obtained, full, but leſs bright, than when raiſed in the weld copper.

Thus by combining different colouring matters with the mordants proper for fixing them on cloth, and alſo with ſubſtances which have the property of reſiſting the blue dye, various coloured paſtes will be obtained.

The ſolutions of tin, from their forming combinations with moſt colouring ſubſtances which are but little affected by acids, ſeem likely to be of conſiderable uſe in the compoſition of paſtes of this deſcription. The muriate of tin deſtroys the reſiſting power of ſolutions of copper by de-oxygenating them; but the nitro-muriate, or highly oxygenated ſolutions, produce rather a contrary effect; they are theſe which ſhould therefore be tried.

Of China Blue.

The proceſs for China blue dipping conſiſts in applying finely ground indigo, in its crude and undiſſolved ſtate, upon the cloth, and fixing it by alternate immerſions in ſolutions of ſulphate of iron and lime.

The ſame thing takes place upon the cloth, that is effected in the ordinary blue vat when indigo is diſſolved; in both caſes the indigo is de-oxygenated, and prepared for ſolution by the copperas, and afterwards diſſolved by the lime.

The different ſhades of colour in China blue dipping are produced by reducing, more or leſs, the ſtandard colour, which is prepared in the following manner.

1ſt. Grind in a metal pot with balls, or by any other contrivance, 10 lbs. of good indigo, 8 lbs. of good copperas, and 5 lbs. of orpiment, with 2 gallons of water; when the whole is nearly ground, add two quarts of very thick ſolution of gum ſenegal, and grind a few hours longer.

2d. Prepare a ſolution of ſulphate of iron by diſſolving 2 lbs. in a gallon of water, adding a quarter of an ounce of pot-aſhes, and ſuffering the precipitate, if there is any, to ſubſide. Reduce the ground blue (No. 1) with as much of this clear ſolution (No. 2) as will bring it to a proper conſiſtence for working, and print with this for the dark full blue. When dipped, this colour will have nearly the effect of black, eſpecially in ſmall bodies.

For pale blue, reduce the ſtandard with 10, 15, or 20 meaſures of the ſolution of copperas, and an equal quantity of acetate of iron, or common iron liquor thickened with gum. With 50, 60, or even 90 meaſures of ſulphate and acetate of iron, one meaſure of the ſtandard blue will give very good ſhades of pale blue. When the pattern, whether block or plate, will not work in gum, a portion of the acetate of iron muſt be thickened with ſtarch, or flour, and ground up in the mill with its due proportion of the ſtandard. When worked on plates, wooden doctors, eſpecially lime tree, are preferred to ſteel ones; they clean the plate much better, and give a fine neat impreſſion.

The vats are of the ſame form, and generally of the ſame dimenſions, as thoſe before deſcribed; they are, however, never lined with lead; wood, or ſtone, being conſidered ſufficiently ſecure for ſolutions of little value, compared with thoſe of indigo. They are diſpoſed in a line, a copperas vat, and a lime vat alternately; or when the mode of dipping allows it, a lime vat between two copperas vats, forming a ſyſtem in which two frames are worked; the lime vat being thus kept conſtantly employed, the copperas vats only alternately. The copperas vats are made up of different ſtrengths, according to the work intended to be done; ſtrong thick goods, ſuch as Marſeilles quilting, &c. require ſtronger vats than calicoes and muſlins. The firſt require the ſolution to be of ſpe. gravity 1040, the latter about 1030. Theſe are the moſt economical points, but good work may be done at any point between 1025 and 1050. Lower than 1025, the colour will be pale and faint, though even; and higher than 1050, it is liable to be uneven, ſome parts being very deep and full, and others meally and ſpoiled.

The lime vats are ſet with fine ſifted quick lime, recently ſlaked, in the proportion of 150 lbs. to 1000 gallons of water.

When the pieces are hooked, and properly arranged on the frame, they are entered firſt into the lime, and the dipping proceeds as follows.

1.	Entry in the lime vat	5	minutes.
2.	in copperas vat	30	
3.	in lime vat	10	
4.	in copperas vat	30	
5.	in lime vat	20	
6.	in copperas vat	45	
7.	in lime vat	45	

During the firſt five minutes in the lime, the frame muſt be gently rocked, or moved up and down, then drawn up and tightened. The vat, both now, and at every ſubſequent dip, is well raked up before the frame is entered. When entered

in the copperas vat, rock five or ſix times, to detach the looſe lime from the piece.

At the ſecond entry in the lime, rock the whole time.

At the ſecond, and every ſucceeding entry in the copperas vat, rock five or ſix times as before, to detach the lime.

At the third and fourth entry in the lime, rock five or ſix minutes, and now and then.

The reaſon for finiſhing out of the lime, is to keep the frames and hooks free from the ruſt and incruſtation of the copperas, which it looſens, and renders more eaſy to detach and clean; with reſpect to raiſing the colour, it makes no difference whatever.

When the piece comes from the copperas vat the ſecond time into the lime, it will appear a graſs green colour, if there be a proper quantity of lime in the vat. If too little, the piece will appear yelloviſh, and more lime muſt be added.

Take off the pieces quickly after the laſt dip, and winch them briſkly in the water-pit a minute or two at the moſt. Get them into the ſours, and after winching over twice or thrice, let them lie an hour or two, after which winch again four or five times, and waſh well in the wheel. Hot water them, and wheel again before hot ſouring, which is done in a ſour of ſpec. gravity 1015, heated to 180°. Winch the goods four or five minutes in this, after which waſh, hot water, &c. and finiſh for drying.

If the goods are kept too long out of the cold ſour after the laſt dip, the oxyd of iron, with which they are coated, oxygenates very rapidly, and the cloth becomes buff or orange. It is with difficulty that the iron is diſengaged, and not without long and very ſtrong hot ſouring.

The cold ſours ſoon become foul with the looſe ſuperfluous indigo, which is detached, and unfits them for light goods, long before the acid is ſaturated.

In this caſe it is economical to add two or three ſhovels full of fine well-beaten clay, previouſly mixed up with water; when this is well incorporated with the ſours, and ſuffered to ſubſide, it carries down with it great part of the floating indigo, and renders them fit for uſe again.

After every day's work the lime and copperas vats muſt be refreſhed.

From 25 to 35 lbs. of ſifted lime, according to the ſize of the vat, and the number of pieces that have been paſſed through it, muſt be added every night.

No harm can ariſe from exceſs of lime, excepting the unneceſſary expence of more than is required, and the accumulation of ſediment or mud in the vat which will ſoon require removing.

Ten pounds of copperas are generally added for every piece of calico that is dipped. This is ſuſpended at the ſurface in a wicker baſket, and ſuffered to remain till all is diſſolved. It is quite unneceſſary to rake up the vat, as the freſh additions of copperas will incorporate uniformly without ſtirring, which, by muddying the vat, may do miſchief. Care muſt be taken to uſe the hydrometer frequently to correct any deficiency or exceſs which may ariſe in the ſp. gr. of the ſolution of ſulphate of iron.

In making new or freſh copperas vats, after having brought them to the ſtandard on the hydrometer, add to every 1000 gallons four or five gallons of the lime vat (raked up) and one pound of potaſh. This is to neutralize the ſuperabundant acid of the copperas.

The graſs green Yorkſhire copperas is the beſt for this purpoſe, it contains the leaſt free acid; the pale whitiſh green is the worſt, and when ſuch is uſed it will be proper occaſionally to throw into the vat about one pound of potaſh, and four or five gallons of muddy lime water.

When daily worked the lime vats ſhould be emptied out, and wholly renewed once a month at leaſt.

The copperas vats are never wholly emptied, but when the mud accumulates ſo as to be troubleſome and endanger the ſafety of the work by reſting on the lower edge of the piece, it muſt be taken out with a ſcoop or ſhovel proper for the purpoſe.

The ground of thoſe goods which ſhew much white will in general be ſufficiently clear when finiſhed according to the preceding directions, the white is however greatly improved by a gentle ſoaping, and one or two days expoſure on the graſs.

In general, better work may be produced in the winter months than in ſummer: in hot weather, the colour is liable to be uneven, patched and meally, the cauſe of this has not been well aſcertained, though, in all probability, it ariſes from the increaſed action of the ſulphate of iron and lime at an increaſed temperature: it is not unlikely that weaker copperas vats would be found to act better in ſummer than ſtrong ones, as the effect of temperature would thereby in ſome degree be counteracted.

From the nature of the proceſs of China blue dipping, it muſt be evident that it muſt precede any other application of colours to which the cloth is intended to be ſubjected. If, for inſtance, reds or yellows are to be introduced, theſe muſt follow the operation of dipping; as they would inevitably be ruined by repeated immerſion in copperas and lime, or wholly diſcharged by cold and hot ſouring.

Dipping, in *Magnetics*, is a certain degree of inclination, which a magnet or magnetic body, be it natural or artificial, endeavours to attain in moſt parts of the world. Amongſt the properties of a magnet, this of its dipping undoubtedly is one of the moſt admirable; but with a magnet already poſſeſſed of its characteriſtic properties, this dipping is not eaſily diſcerned; it being difficult to ſay, whether the inclination of one of its extremities below the horizontal plane, and of courſe the elevation of its oppoſite extremity above that plane, is owing to the magnetic virtue, or to the want of mechanical balance, (*viz.* to its being heavier on one ſide of the fulciment than on the other,) and it was evidently on this account that the dipping of the magnet was not diſcovered ſo ſoon as its property of directing itſelf north and ſouth, or nearly ſo. See Magnetism.

The eaſieſt method of obſerving this magnetical property is as follows. Suſpend an oblong and *unmagnetic* piece of ſteel either upon a vertical pointed wire, after the manner of a common compaſs-needle, or by faſtening a fine thread to its middle; ſo that the oblong piece of ſteel may remain perfectly balanced, and of courſe horizontal. (A common oblong ſewing-needle, having a thread faſtened to its middle, will anſwer ſufficiently well.) Then let this piece of ſteel or needle be rendered magnetic by the mere application of two powerful magnetic bars to its extremities; taking particular care not to diſturb its point of ſuſpenſion; and when this has been done, and the magnets have been removed, the piece of ſteel or needle will no longer remain in an horizontal ſituation, but one of its extremities will dip; that is, will incline itſelf below the horizontal plane, and its oppoſite extremity will raiſe itſelf above that plane, making an angle with it which is different in different parts of the world, and in ſome places it vaniſhes; that is, the needle will remain horizontal. This angle is alſo various in the ſame fixed place at different times; this latter variation however is but trifling. In England, the north end of the magnet tends downwards. A clearer idea of the different inclinations of the magnet, or magnetized ſteel, in different parts of the world, as well as

of the cauſe upon which that phenomenon depends, may be derived from the following experiment. Take a globular magnet, N S, *Plate* IV. *Magnetiſm, fig.* 22, commonly called a *terrella*, or a magnetic ſteel bar, N S, *fig.* 23. (for by drawing a circle round the latter, one may eaſily figure to himſelf the form of a globular magnet.) The extremity N of this terrella, or ſteel bar, is its north pole, and the extremity S its ſouth pole; and A is its middle or equator. Place it upon a table as C D; then take another ſmall and oblong magnet, or a common ſewing-needle rendered magnetic; ſuſpend it by faſtening a fine thread to its middle, in ſuch a manner as to remain in an horizontal poſition when not influenced by any other magnet. Now, if the ſaid ſmall magnet, being held by the upper part of the thread, be brought juſt over the middle of the large magnet, within two or three inches of it; you will find that it will turn itſelf ſo as to direct its ſouth pole *s* towards the north pole N of the large magnet, and its north pole *n* towards the ſouth pole S of the large one; it being a well-known law in magnetics, that poles of different denominations attract each other. It will be farther obſerved, that the ſmall magnet, whilſt kept juſt over the middle A of the large magnet, will remain parallel to it or to its magnetic axis; for in that caſe the poles of the ſmall magnet are equally attracted by the contrary poles of the large magnet, which are equidiſtant from the former. But if the ſmall magnet be moved a little nearer to one end than to the other of the large magnet, then one of the poles of the former, namely, that which is neareſt to the contrary pole of the latter, will incline itſelf towards it; and of courſe the other extremity will be elevated above the horizon. This inclination of the ſmall magnet will be found to increaſe in proportion as it is brought nearer and nearer to one of the poles N or S; and, at laſt, if it be brought directly oppoſite to one of thoſe poles, it will turn its contrary pole towards it, and will place itſelf in the ſame ſtraight line with the axis of the large magnet, as is indicated by the figures 22 and 23, wherein the like parts are denoted by the ſame letters.

It muſt now be obſerved, that all the facts that have hitherto been noticed relative to the ſubject of magnetiſm, tend to prove, that the whole earth is, or muſt be conſidered as a large magnet; having its magnetic poles, magnetic equator, &c.: hence a magnetic needle, or any other magnet whatever, ſituated on different parts of the earth's ſurface, inclines, or tends to incline, the one or the other of its extremities, towards the horizon, or towards the axis of the earth, in the ſame manner and for the ſame reaſons that compelled the ſmall magnet *n s* of the preceding experiment to aſſume its various directions when placed in the vicinity of the large magnet N S. For, admitting that the north pole of the earth is poſſeſſed of a ſouth magnetic polarity, and that the oppoſite pole is poſſeſſed of a north magnetic polarity, it follows, as is confirmed by actual experience, that when a magnet, properly ſhaped and properly ſuſpended, is kept near the equator of the earth, it muſt remain in an horizontal ſituation; that if it be moved nearer to one of the poles of the earth, it muſt incline one of its extremities; namely, that which is poſſeſſed of the contrary magnetic polarity; that the ſaid inclination muſt increaſe in proportion as the magnet, or magnetic needle, recedes from the equator of the earth; and, laſtly, that when brought juſt over either of the magnetic poles of the earth, it muſt ſtand perpendicular to the ground; *viz.* in the ſame ſtraight line with the axis of the earth.

The reader muſt not be ſurpriſed to hear that a ſouth magnetiſm is attributed to the north pole of the earth; it being only meant, that it has a magnetic polarity contrary to that end of the magnetic needle which is directed towards it; and as we call the ſame end of the needle a north magnetic pole, we muſt of neceſſity attribute a contrary power, that is, a ſouth magnetic polarity, to the northern part of the earth.—With a proper change of names, the ſame remark muſt be applied to the ſouthern part of the earth; *viz.* it muſt be conſidered as being poſſeſſed of a north magnetic polarity.

By a little attentive conſideration it will be eaſily comprehended, that the true and natural ſituation of a magnet, or magnetic needle, is a combination of its horizontal and vertical direction; *viz.* the magnetic needle endeavours to place itſelf in the plane of the magnetic meridian, and in a direction more or leſs inclined to the horizon, according as it happens to be ſituated, nearer to or farther from any of the magnetic poles of the earth. And this natural direction of the magnet is called the *magnetical line*. Therefore, in order to obſerve the true dipping of the magnet, the magnetic needle, or oblong magnet, muſt be placed in the magnetic meridian; *viz.* in the uſual direction of the compaſs at the place of obſervation; otherwiſe the inclination of the magnet will be greater than it ought to be, as may be eaſily derived from a due conſideration of the combined forces which act upon it. Hitherto we have conſidered the earth as an uniform and regular magnet, having the magnetic poles in its real poles, and its magnetic equator in its true or aſtronomical equator. And if ſuch were the caſe, the dipping angle, which the magnetic needle makes with the horizon, would bear a certain determined ratio to the latitude of the place; ſo that by obſerving that angle, the latitude of the place might be deduced from it, without the need of any aſtronomical obſervation, which would prove of the utmoſt advantage to navigators; the caſe, however, is far different, as will be more particularly noticed in the ſequel. For the preſent it will be worth while to mention, that after the diſcovery of the dipping property of the magnet, ſanguine expectations were entertained reſpecting the advantages which might be derived from it, and it was imagined, that not only the latitude, but the longitude alſo of the place of obſervation, might be indicated by the dipping angle of the magnetic needle; for though it ſoon appeared, that neither the magnetic poles, nor the magnetic equator, of the earth, coincided with its true poles and true equator; yet that very ſame circumſtance ſeemed to furniſh the method of determining the longitude; which method was grounded upon the following principle; *viz.* that if the magnetic poles, though different from the real poles of the earth, be either fixed in other places, or do move with any regularity, it follows that the magnetic equator muſt likewiſe differ from the real equator; and muſt cut it at a certain angle; therefore, in the ſame parallel of latitude, but in different longitudes, the dipping angle of the magnet muſt be different; hence, by obſerving the dipping angle of the magnet at any particular place, the longitude of the place would thereby be indicated. Impreſſed with this idea, during a long period, ſubſequent to the diſcovery of the dipping of the magnet, the ſcientific world made various and ſtrenuous exertions for the purpoſe of rendering that magnetic property ſubſervient to navigation. Innumerable calculations were made, and various inſtruments were contrived. Mr. Henry Bond, a diſtinguiſhed teacher of the art of navigation in London, calculated a table of latitudes correſponding to every five minutes of the inclination of the magnetic needle, and it was given out, that with this Mr. Bond's table, a good dipping needle, and the latitude of the place of obſervation, one might determine the longitude of any place in the world. Phil. Trans. v. viii. p. 6065. Mr. Bond was not the only projector of the kind. Meſſrs. Ditton, Whiſton, and many others followed his example. Some were poſitive, others doubtful, and a few

cautious perſons patiently awaited the reſult of experience; but the reſult of actual experiments ſoon proved the impracticability, or the inſufficiency, of the projects, which were of courſe gradually neglected, and were laſtly even ridiculed by the facetious Dean Swift. The principal object of calculation is to determine the nature of a curve which might paſs through the poles of a large magnet, and to which curve a ſmall magnetic needle may be a tangent at any point of its courſe. Or, in caſe of the earth, to calculate the inclination which the needle muſt have in any particular point of its ſurface. The data, however, upon which theſe calculations muſt be grounded, are uncertain. The magnetic needle is acted upon by both poles of the earth, and the law of that action is by no means well known; though it appears, both from experiments and calculation, that, moſt probably, the force of each pole varies in the inverſe duplicate ratio of the diſtance. See Mr. Lambert's experiments and calculations in the Memoirs of the Academy of Berlin for 1756, and his ſecond diſſertation in the 22d volume of the ſame. We might refer our readers to other works, and we might alſo inſert proper ſpecimens of the calculations that have been propoſed and actually made; but ſince the projects are neither eſtabliſhed upon unqueſtionable principles, nor are they at all ſatisfactory, we ſhall not ſwell this article by the introduction of intricate inveſtigations.

In ſhort, it appears, from the concurrence of all the moſt accurate experiments and obſervations that have been made upon land as well as at ſea, 1ſt, that the earth is not an uniform or regular magnet, but a very irregular one; for the ferruginous parts of it, (from the joint action of which the magnetiſm of the whole ariſes,) are irregularly diſpoſed through it; whence it ariſes, that according as the magnetic needle is nearer to or farther from any ferruginous matter, ſo it is more or leſs influenced by it. 2dly, the magnetic poles of the earth are neither diametrically oppoſite to each other, nor indeed have philoſophers as yet been able to determine their preciſe ſituations. Profeſſor Krufft, in the 17th vol. of the Peterſburgh Commentaries, places the north magnetic pole of the earth in lat. 70° North, and longitude 23° Weſt of London; and the ſouth magnetic pole in latitude 50° South, and longitude 92° Eaſt. Wilcke of Stockholm, in his indication chart, in the 33d vol. of the Swediſh Memoirs, places the north magnetic pole in latitude 75° North, near Baffin's Bay, in the longitude of California, and the ſouth pole in the Pacific Ocean, latitude 70° S. Churchman places the north pole in latitude 59° N. and longitude 135° W. and the ſouth pole in lat. 59° S. long. 165° E. A planiſphere by the Academy of Sciences at Paris for 1786, places the magnetic equator ſo as to interſect the earth's equator in long. 75° and 155° from the Iſland of Ferro, with an inclination of 12° nearly, making it nearly a great circle. But we are not informed on what authority, nor does this ſtatement agree with the obſervations of the dipping made by Britiſh navigators. Mr. Churchman has given a ſketch of a planiſphere with lines which may be called parallels of the dip. Thoſe parts of each parallel that have been aſcertained by obſervation, are marked by dots, ſo that we can judge of his authority for the whole delineation. The magnetic equator cuts the earth's true equator in long. 15°, and 195° E. of Greenwich obſervatory, at an angle of 17° nearly. The circles of magnetic inclination are not parallel, being conſiderably nearer to each other on the ſhort meridian than on its oppoſite. 3dly, the magnetiſm of the earth, *viz.* the poſitions of its magnetic poles, magnetic equator, &c. are ſubject to a gradual, but uncertain variation, which, in all probability, ariſes from the irregular heating and cooling, from the formation and decompoſition of the different internal parts of the earth, and perhaps from other cauſes.

Notwithſtanding the failure of the advantages which were expected from the dipping property of the magnet, it muſt be acknowledged, that the dipping needle, which ſhews the above-mentioned property of the magnet, ſeems, upon conſideration, to be the principal inſtrument, from the indication of which we may expect to complete the magnetic theory of the terraqueous globe: it is therefore to be wiſhed, that accurate, and at the ſame time leaſt expenſive, inſtruments may be contrived for the purpoſe; and that numerous as well as accurate obſervations may be made with them in every part of the world.

DIPPING-*Needle*, is an inſtrument which ſhews the inclination of the magnet, or the natural direction of that admirable production of nature, at the place in which the inſtrument is ſituated. The obſervations of the dipping property of a magnet, or magnetized body, require much more accurate inſtruments, and much greater attention, than thoſe of the horizontal direction of the compaſs.

Mr. Norman, the firſt obſerver of the magnetical dipping, made a conſiderable number of original obſervations with inſtruments not much capable of accuracy; and, indeed, if the various circumſtances which are capable of rendering the dipping-needle imperfect be duly conſidered, the great difficulty of the conſtruction will be eaſily perceived. The principal parts of a dipping-needle are an oblong piece of ſteel called the *needle*, ſo nicely poiſed upon an horizontal axis, as to remain in any ſituation in which it may be placed when not magnetized: hence, when it is afterwards rendered magnetic, it may place itſelf in that direction which the magnetic virtue alone compels it to aſſume. The inſtrument muſt likewiſe be furniſhed with a divided circle, concentric with the needle's axis of motion, and ſituated ſo as to meaſure the angle which the needle makes with the horizon. But the difficulty of poiſing a needle, with ſuch a perfect coincidence of its centre of gravity with its axis of motion, is very great; and even when this object is accompliſhed, the introduction of dirt or duſt, either between the axis and ſurface upon which it reſts, or upon the needle itſelf, will eaſily derange the whole. It is likewiſe difficult to make the obſervations free from error; for inſtance, if the needle, moveable only in a vertical plane, be not ſet in the plane of the magnetic meridian, it will always dip too much. At London, where the magnetic dip makes an angle of about $72\frac{1}{2}°$ with the horizon, if the dipping-needle be ſituated in a plane 20° diſtant from the magnetic meridian, it will ſtand nearly perpendicular to the horizon; for in this caſe the needle, agreeably to the mechanical reſolution of forces, will place itſelf in the ſituation which brings it neareſt to the true magnetic meridian. It is probably owing to this kind of inaccuracy, that the obſervations of the dip, made by Norman and other contemporary obſervers, ſeem to give the dip much greater than they ought to do.

The general mode of conſtructing the dipping-needle, or the ſimpleſt conſtruction of the inſtrument, conſiſts of an oblong piece of flat ſteel, called the needle, broader in the middle, and tapering towards the extremities. An axis paſſes through the middle of it, and its extremities move in two holes, ſo that the needle can move edgeways, upwards and downwards, like the beam of a pair of ſcales. Two lateral bars, in which the holes for the extremities of the axis are made, are faſtened to a divided circle, which is to indicate the angle which the needle makes with the horizon. The divided circle, with the lateral bars and needle, are fixed

fixed upon a pedeſtal, which may be placed duly horizontal by means of ſcrews and a level or two.

Fig. 24. (*Plate* IV. *Magnetiſm*) repreſents this inſtrument in its ſimpleſt ſtate. A B is the needle, the axis of which, E F, reſts upon the middle of the two lateral bars C D, C D, which are made faſt to the divided circle, E F. G is the ſtand which ſupports the whole, and which is furniſhed with three ſcrews and a ſpiral level. With ſuch a ſtand the inſtrument is to be uſed upon land; but at ſea the inſtrument, without the ſtand, is ſuſpended by a ring H, to a proper frame, ſo as to hang perpendicularly in the plane of the magnetic meridian, the ſituation of which is ſhewn by a common compaſs.

The beſt method of obſerving the dip, is to place the needle in the magnetic meridian by means of a common compaſs, taking care to place the two inſtruments ſufficiently diſtant from each other, leſt they ſhould influence each other's movements. Then obſerve the angle which the dipping-needle makes with the horizon. Sometimes the frame, which contains the dipping-needle, is furniſhed with two ſight vanes on an index, which moves horizontally on the top of the frame, and through thoſe ſights a diſtant object, the bearing of which is exactly known, may be kept in view, in order to ſituate the dipping-needle in the magnetic meridian.

With ſuch an inſtrument the error of obſervation, which may ariſe from the poſſible want of balance in the needle, is uſually removed in the following manner:—After having obſerved the dip, with one end of the needle downwards, the magnetiſm of it is reverſed by the application of magnetic ſteel bars (ſee MAGNETISM); ſo that the end which had the north polarity may now be poſſeſſed of the ſouth polarity, and *vice verſâ*. Then the dip is obſerved again with the other extremity of the needle downwards; and a mean of the two obſervations is taken as the true or correct dip. Beſides this, the needle may be turned with each of its two flat ſurfaces, alternately to the right and to the left, ſo as to make, altogether, four obſervations; a mean of which will come much nearer to the truth.

It is almoſt uſeleſs to remark, that in the conſtruction of ſuch inſtruments, as well as in making the obſervation, no iron, ſteel, or other ferruginous matter, muſt be ſuffered to be in the frame, or about it, ſince a very ſmall quantity of it is ſufficient to render the obſervation erroneous.

A great imperfection in the dipping needle ariſes from the different forces with which the magnetiſm of the earth acts upon its two extremities, in different degrees of inclination. This ſource of error will be illuſtrated by *fig.* 25. Let A B be the dipping-needle; the circle E F repreſents one end of its axis; the lower part, F, of which reſts upon the ſupport C D; and E F is the line which paſſes through the centre of the needle, and divides it into two equal parts. It is evident, that before the needle has acquired any magnetiſm, if it be of an uniform figure, and its axis be truly cylindrical, the needle muſt remain in any ſituation in which it happens to be ſituated, ſince the perpendicular, raiſed from the point where the axis E F touches the fulcimen C D, paſſes always through the centre of the needle, and divides it into two equal parts; whence the needle becomes perfectly balanced in any degree of inclination. But though the needle be perfectly balanced, yet it is manifeſt, that in an inclined ſituation, as ſhewn in *fig.* 26, the part of it, G A, which ſtands above the point of reſt G, is longer than the part B G, which ſtands below it; and this difference increaſes according as the inclination increaſes, becauſe the axis of the needle is not a mathematical line, but a body of a certain diameter; ſo that, when the needle ſtands in a perpendicular ſituation, that part of it, which lies above the ſupporting plane, exceeds the other part juſt by the diameter of the axis. Now when the needle is inclined, as in *fig.* 26, ſuppoſe that two equal and like forces be applied to its extremities A and B, it is evident, that the force applied to the extremity A, muſt have more power to move the needle than that which is applied to B, becauſe G A is the longer lever of the two. This inequality of effects muſt evidently increaſe according as the inclination increaſes, and is greateſt when the needle ſtands in a perpendicular ſituation. The application of theſe forces takes place when the needle has been rendered magnetic; for, as the greateſt attractive and repulſive powers, between the magnetic poles of the earth and the poles of the needle, act upon the extremities A and B, the above-mentioned irregularity muſt increaſe with the inclination of the needle, and with the degree of its magnetic power. No effectual method of removing this cauſe of error has, as yet, been deviſed.

Having premiſed a ſufficient idea of the general conſtruction, and the common imperfections of this delicate magnetical inſtrument, it is now neceſſary to deſcribe the beſt or moſt improved inſtruments of the kind, and to ſubjoin the moſt approved precautions, which ſhould be obſerved in the uſe and management of the ſame.

In the year 1772, Mr. Nairne completed two dipping needles for the Board of Longitude, agreeably to a plan of the Rev. Mr. Mitchell, a gentleman eminently diſtinguiſhed for his great knowledge in magnetics. Not long after, the ſame artiſt conſtructed a ſimilar inſtrument for the Royal Society; which, however, differed in ſome particulars from the former. They are all remarkably well made; but we ſhall firſt deſcribe one of the former; for it will afterwards be eaſy to point out the few particulars in which the dipping needle of the Royal Society differs from them. *Fig.* 27. is a delineation of one of the needles, made for the Board of Longitude. A A is the needle, whoſe length is twelve inches. B, B, are the ends of its axis, which reſt upon the four friction wheels, C, C, C, C. The ends of the axis of the needle, as well as thoſe of the axes of the friction wheels, are made of gold alloyed with copper, and they all bear againſt flat pieces of agate, D, D, D, finely poliſhed. The ends of the axes, of the wheels, move in holes made in bell metal. E E E is the circle of bell-metal, which is divided into degrees and half-degrees, for the purpoſe of ſhewing the angle which the needle makes with the horizon. It is hardly neceſſary to obſerve, that the centre of the needle coincides with the centre of the divided circle. In reading off the angle, &c. the meaſure of it was expreſſed in degrees and minutes; but the minutes were reckoned by eſtimation; for inſtance, the third part, or what appeared to be the third part of half a degree, was reckoned ten minutes; the half was reckoned fifteen minutes, and ſo forth. The needle was nearly balanced before it was rendered magnetic; but it may be adjuſted after impregnation, by means of a croſs of wires, F, F, F, F, which was the contrivance of the Rev. Mr. Mitchell, and is affixed to the axis of the needle. Each of the wires, which form the arms of this croſs, is cut with a fine ſcrew, to receive a ſmall weight, or button, which may be ſcrewed nearer to, or farther from, the axis of motion; whence the needle may be adjuſted both ways with great nicety, by reverſing the poles, and changing its ſides. G, G, are two levels, which ſerve to ſet the line of 0 degrees truly horizontal. H is the perpendicular axis, whereby the inſtrument may be turned ſo that the divided face of the inſtrument may front either the eaſt or the weſt. I is an index, fixed to the perpendicular axis H, and which points to an

oppoſite

oppoſite line on the horizontal plate K, when the inſtrument is turned half round. L, L, L, L, are four adjuſting ſcrews, to ſet the inſtrument properly. One of theſe ſcrews is hid behind the circle. M, M, M, M, are ſcrews which hold the glaſs-cover, to prevent the diſturbance of the needle by the wind.

The 66th volume of the Philoſophical Tranſactions contains an account of the meteorological inſtruments uſed at the Royal Society's houſe, by the Hon. Henry Cavendiſh; and in that part of this account, which treats of the conſtruction and management of the dipping needle, Mr. Cavendiſh expreſſes himſelf in the following manner:

"In this inſtrument, the ends of the axis of the needle roll on horizontal agate planes, a contrivance being applied, by which the needle is at pleaſure lifted off from the planes, and let down on them again, in ſuch a manner as to be ſupported always by the ſame points of the axis, reſting on the ſame parts of the agate planes; and the motion with which it is let down is very gradual and without ſhake. The general form of the inſtrument, the ſize and ſhape of the needle, and the croſs uſed for balancing it, are the ſame as in the dipping-needle deſcribed in the Phil. Tranſ. vol. 62. It is alſo made by the ſame artiſt, Mr. Nairne.

"It may be ſeen in the Meteorological Journal, that the dip was obſerved firſt with the front of the inſtrument to the weſt, and then to the eaſt; after which the poles of the needle were reverſed, and the dip obſerved both ways as before. The reaſon of this is, that the mean of the obſerved dips, in theſe four ſituations, differs very little from the truth, though the needle is not well balanced, and even though a great many other errors are committed in the conſtruction of the inſtrument; provided the needle is made equally magnetical after the poles are reverſed as before; (it is eaſy to ſee whether the needle is made equally magnetical after the poles are reverſed as before, by counting the number of vibrations which it makes in a minute;) and that the difference of the obſerved dip, in theſe four ſituations, is not very great, as will appear from the following conſiderations."

"Firſt, let *fig.* 28. be a front view of the needle; AB a line parallel to the direction of magnetiſm therein; and CD a perpendicular thereto, meeting it in the line joining the centres of the cylindrical ends of the axis, or in the axis of motion, as we may call it. If the needle was truly balanced, its centre of gravity would be in *d*, the interſection of A B and C D. Suppoſe now, that the needle is not truly balanced, but that its centre of gravity is in *g*; draw *g n* perpendicular to A B, cutting it in *m*; and let the parts *m n* and *m g* be equal. When the inſtrument is turned half way round, ſo that the contrary face of the needle is preſented towards us, the edge, ADB, which is now loweſt, will become uppermoſt, and the centre of gravity will be in that ſituation in which the point *n* now is; therefore, the mean between the forces with which the needle is drawn out of its true poſition in theſe two ſituations, in conſequence of its not being truly balanced, is accurately the ſame; and the mean between the two obſerved dips is very nearly the ſame, as if the centre of gravity was at *m*. But if the centre of gravity is at *m*, the dip will be very nearly as much too great in the preſent ſtate of the needle, as it will be too little when the poles are reverſed. Therefore, the mean of the obſerved dips in theſe four ſituations will be very nearly the ſame as if the needle was truly balanced.

"Secondly, if the planes on which the axis rolls are not horizontal, the dip will be very nearly as much greater than it would otherwiſe be, when one face is turned to the weſt, as it is leſs when the other is; for if theſe planes dip towards the ſouth in one caſe, they will dip as much towards the north in the other, ſuppoſing the levels by which the inſtrument is ſet, to remain unaltered. Conſequently, the mean of the two obſervations will be very nearly the ſame as if they were placed truly horizontal.

"Thirdly, by the ſame method of reaſoning it appears, that the mean of the two abovementioned obſervations will be not at all altered, though the line, joining the mark on that end of the needle by which we obſerve, with the axis of motion, is not parallel to the direction of magnetiſm in the needle; that is, though the mark does not coincide with the point A or B, or though the line joining the two diviſions of 90° is not perpendicular to the horizon, or though the axis of motion does not paſs through the centre of the divided circle, provided it is in the ſame horizontal plane with it. If, indeed, the axis of motion is not in the ſame horizontal plane with the centre of the divided circle, the error proceeding from thence will not be compenſated by this method of obſerving, unleſs both ends of the needle are made uſe of. This, however, is of no conſequence, as it is eaſy to examine whether they are in the ſame horizontal plane or not.

"But the error which is moſt difficult to be avoided is, that which proceeds from the ends of the axis being not truly cylindrical. I before ſaid, that the parts of them which reſt on the agate planes are always exactly the ſame. The inſtrument is ſo contrived, however, that we may on occaſion, by giving the axis a little liberty in the notches by which it is lifted up and down, make thoſe planes bear againſt a part of the axis diſtant about $\frac{1}{100}$th or $\frac{1}{50}$th of an inch from their uſual point of bearing. Now, I find, that when the axis is confined ſo as to have none of this liberty, and when care is taken, by previouſly making the needle ſtand at nearly the right dip, that it ſhall vibrate in very ſmall arches when let down on the planes; that then, if the needle is lifted up and down any number of times, it will commonly ſettle exactly at the ſame point each time, at leaſt the difference is ſo ſmall as to be ſcarcely ſenſible; but if it is not ſo confined, there will often be a difference of 20′ in the dip, according as different parts of the axis reſt on the planes; and that, though care is taken to free the axis and planes from duſt as perfectly as poſſible, which can be owing only to ſome irregularity in the axis. Moreover, if the needle vibrates in arches of five or more degrees, when let down on the planes, there will frequently be as great an error in the dip. It is true, that the part of the agate planes, which the axis reſts on when the vibrations are ſtopped, will be a little different according to the point which the needle ſtood at before it was let down; which will make a ſmall difference in the dip as ſhewn by the divided circles, when only one end of the needle is obſerved, though the real dip or inclination of the needle to the horizon is not altered; but this difference is by much too ſmall to be perceived; ſo that the abovementioned error cannot be owing to this cauſe. Neither does it ſeem owing to any irregularity in the ſurface of the agate planes, for they were ground and poliſhed with great accuracy; but it moſt likely proceeds from the axis ſlipping in the large vibrations, ſo as to make the agate planes bear againſt a different part of it from what they would otherwiſe do. I have great reaſon to think, that this irregularity is not owing either to want of care or ſkill in execution; but to the unavoidable imperfection of this kind of work. I imagine too, that this inſtrument is at leaſt as exact, if not more ſo, than any which has been yet made."

We ſhall now ſubjoin a ſtatement of experiments carefully made

made with one of the abovementioned needles, conſtructed by Nairne for the Board of Longitude, whence the reader will be enabled to judge of the accuracy which may be expected from theſe obſervations, and of the particulars which muſt be attended to in making thoſe obſervations.

Firſt ſet of experiments made by Mr. Nairne. In theſe experiments the needle being placed, as nearly as poſſible, in the magnetic meridian, was raiſed to an horizontal poſition, and left to vibrate. It was between eight and nine minutes before the vibration ceaſed. In ſix experiments the dipping needle conſtantly ſhewed an angle of 72° 20′, with the horizon.

Second ſet of experiments, with that ſide of the inſtrument to the eaſt, which was to the weſt in the firſt obſervations. The needle made an angle of

72° 10′
72 15
72 45 } Here the ends of the axis
72 45 } touched the agates.
72 5
72 0

Third ſet of experiments, in which the poles of the needle were reverſed, but the ſame ſide of the inſtrument to the eaſt, as in the ſecond ſet of experiments, and the needle rather more magnetical, being touched with a larger ſet of magnets. In ſix experiments the dip was conſtantly 72° 30′.

Fourth ſet of experiments; *viz.* the ſame ſide of the inſtrument to the eaſt, as in the firſt ſet of experiments. The dipping angle made by the needle with the horizon was

72° 10′
72 10
72 15
72 10
72 10
72 10

Fifthly, the ſame end of the needle being made north, as in the firſt ſet of experiments, and alſo the ſame ſide of the inſtrument to the weſt, as in the firſt ſet of experiments, the dipping angle was 72° 20′.

The reſults of the above experiments undoubtedly coincide with each other in a remarkable degree; but ſeveral other experiments of a ſimilar nature, made with the ſame or with ſimilar inſtruments, have by no means been attended with the ſame remarkable coincidence; and this is particularly to be remarked in the account of Mr. Hutchins's obſervations on the dipping-needle, made at Albany Fort, in 1775, as is ſtated in the 66th vol. of the Phil. Tranſ. page 179, where the obſervations, made on the very ſame day, differ by four degrees and upwards.

Mr. Daniel Bernoulli has ſhewn the method of conſtructing a pretty ſimple dipping-needle, which is capable of conſiderable accuracy on ſhore. The conſtruction is as follows: "Let a dipping-needle be made in the beſt manner that can be done by a workman of the place, and balanced with ſome accuracy before impregnation, ſo that we may be certain that when rendered magnetic it will take nearly the true dip. Touch it (*viz.* magnetize it) and obſerve the dip. Deſtroy its magnetiſm, and then alter its balance in ſuch a manner as to render it capable of arranging itſelf in the magnetical line, or in the direction of the obſerved dip, though it be not poſſeſſed of magnetiſm. Now touch it again, giving it the ſame poles as before. It is plain that it will now approach exceedingly near to the true dip, becauſe its want of perfect equilibrium deranged it but a few degrees from the proper direction. Should this ſecond obſervation of the dip differ ſeveral degrees from the firſt, by the inaccurate formation of the needle, it will be proper to repeat the operation, which, however, will ſeldom be neceſſary. Mr. Bernoulli makes this ſimple contrivance anſwer the purpoſe of an univerſal inſtrument in the following ingenious manner. A very light braſs graduated circle E F G, (*Plate* IV. *Magnetiſm, fig.* 29.) is fixed to one ſide of the needle concentric with its axis, and the whole is balanced as nicely as poſſible before impregnation. A very light index C D is then fitted on the axis, ſo as to turn rather ſtiffly on it. This will deſtroy the equilibrium of the needle. If the needle has been made with perfect accuracy, and perfectly balanced, the addition of this index would cauſe it always to ſettle with the index perpendicular to the horizon, whatever degree of the circle it may chance to point at. But as this is ſcarcely to be expected, ſet the index at various degrees of the circle, and note what inclination the magnetic needle takes for each place of the index, and record them all in a table. Suppoſe, for example, that when the index is at 50°, the needle inclines 46°, from the horizon. If in any place we obſerve that the needle (rendered magnetic by lying between two ſtrong magnets) having the index at 50, inclines 46°, we may be certain that this is the dip at that place; for the needle is not deranged by the magnetiſm from the poſition which gravity alone would give it. As we generally know ſomething of the dip that is to be expected in any place, we muſt ſet the index accordingly. If the needle does not ſhew the expected dip, alter the poſition of the index, and again obſerve the dip. See whether this ſecond poſition of the index and this dip form a pair which is in the table. If they do, we have got the true dip. If not, we muſt try another poſition of the index. Noticing whether the agreement of this laſt pair be greater or ſmaller than that of the former pair, we learn whether we are to change the poſition of the index in the ſame direction as before, or in the oppoſite.

A needle of this kind in the hands of an experienced philoſopher was found to anſwer remarkably well. It is a contrivance worthy of its ingenious author, and deſerves to be recommended, becauſe it may be made for a moderate price, and of courſe it may afford the means of multiplying the obſervations of the dip, which are of the utmoſt conſequence in the theory of magnetiſm.

We have now deſcribed the beſt and moſt approved conſtructions of an inſtrument, to which too much attention cannot be paid either by the artiſt who conſtructs it, or by the obſerver who uſes it; and we have pointed out the difficulties which muſt be overcome, as well as the precautions which muſt be attended to by both. But moſt of theſe obſervations relate to the uſe of the dipping-needle upon land. At ſea the difficulty of making accurate obſervations with the dipping-needle, is obviouſly much greater, conſidering the unſteadineſs of the ſituation. The beſt contrivance for the purpoſe of rendering the dipping-needle more manageable at ſea, was made by Dr. J. Lorimer, and the deſcription of it, which we ſhall now ſubjoin, is publiſhed in the 65th volume of the Phil. Tranſ. In this conſtruction the needle ſhews, at the ſame time and by itſelf, the horizontal and vertical direction of the magnet, or, more properly ſpeaking, places itſelf in the magnetical line: whereas the dipping-needles, which we have deſcribed in the preceding pages, require to be ſituated in the magnetic meridian. In ſhort, this needle of Dr. Lorimer anſwers at once the purpoſes of a dipping-needle, and of a common compaſs. *Fig.* 30. is a repreſentation of this dipping-needle. "Whenever," Dr. Lorimer ſays, "any one meets with a terrella, or ſpherical load-ſtone, the firſt thing he does is to find out its poles; and having once diſcovered them, he knows immediately how any ſmall bits of needle will

will be affected, if it is placed upon any part of the ſurface of that terrella. The poles are moſt readily diſcovered by trying where the filings of iron, or a ſmall bit of needle, will ſtand erect upon the terrella; and this is generally found to be upon two points which are diametrically oppoſite to one another. But the magnetic poles of the earth ſeem to be placed obliquely to one another (ſee the Berlin Memoirs, 1757); though where they are actually ſituated is hitherto unknown; whether they are upon land or water; or, in either caſe, whether we can come nigh to them. Yet, be theſe things as they may, it appears evident to me, that accurate obſervations, made as near to thoſe magnetic poles as poſſible, with a good dipping needle, is the ſureſt way to complete the magnetic theory of this globe, analogous to the method we purſue in examining the terrella. But, as all the dipping needles which I have ſeen, appeared to me to be very ill calculated for the ſea ſervice at leaſt, I contrived one upon a different plan in 1764, and had it executed before I left England by Mr. Siſſon. I have called it an *univerſal magnetic needle*, or *obſervation compaſs*, becauſe I can by it take the dip and amplitude, and even the azimuth, with only one aſſiſtant to take the altitude for me. The needle is of the ſame ſhape and ſize nearly as thoſe uſed now for the compaſſes of the royal navy, and plays vertically upon its own axis, which has two conical points, ſlightly ſupported in two correſponding ſockets, which are inſerted into the oppoſite ſides of a ſmall upright braſs parallelogram, about one inch and a half broad, and ſix inches high. Into this parallelogram is fixed, at right angles, a ſlender braſs circle, about ſix inches diameter, ſilvered, and graduated to every half degree, upon which the needle ſhews the dip, by a vernier, if you chooſe; and this, for the ſake of diſtinction, I ſhall call the *circle of magnetic inclination*. This braſs parallelogram, and, conſequently, the circle of inclination, alſo turns horizontally upon two other pivots, the one above and the other below, with correſponding ſockets in the parallelogram. Theſe pivots are fixed in a vertical braſs circle, of the breadth and thickneſs of two-tenths of an inch, and of ſuch a diameter, as to allow the circle of inclination and the parallelogram to move freely round within it. This ſecond circle I ſhall call the *general meridian*. It is not graduated, but has a ſmall braſs weight fixed to the lower part of it, to keep it upright; and the circle itſelf is ſcrewed, at right angles, into another circle, of equal internal diameter, of the ſame thickneſs, and twice the breadth, which is ſilvered, and graduated on the upper ſide to every half degree. It repreſents the horizon as it ſwings freely upon gimbalds, and is always nearly parallel to it. The whole is contained in a neat mahogany box, of an octagon figure, with a glaſs plate at top, and one on each ſide, for about two thirds down. That part of the frame which contains the glaſs lifts off occaſionally. The whole box turns round upon a ſtrong braſs centre, fixed in a double plate of mahogany, glewed together croſs-wiſe, to prevent its warping or ſplitting; and this again is ſupported by three braſs feet, ſuch as are uſed for caſes of table knives, froſted, that they may not eaſily ſlip, if the veſſel ſhould have any conſiderable motion. It has another ſquare deal box to lock it up in, to preſerve the glaſs, &c. when it is not wanted for uſe.

"The uſe of this inſtrument is very plain, as the inclination, or dip, is at any time apparent from inſpection only; and alſo the variation, if the frame is turned round till the great vertical circle lies exactly in the plane of the true meridian: for, the circle of inclination being always in the needle's vertical plane, the edge of it will evidently point out upon the horizon the variation eaſt or weſt. But at ſea, when there is not too much motion, you turn the frame round till the vertical circle is in the plane of the ſun's rays; that is, till the ſhadow of the one ſide of it juſt covers the other, and the edge of the circle of inclination will then give the magnetic amplitude, if the ſun is riſing or ſetting; but the azimuth at all other times of the day; and, the true amplitude or azimuth being found, in the uſual way, the difference is the variation. If the motion is conſiderable, obſerve the extremes of the vibration, and take the mean for your magnetic amplitude, or azimuth. When the ſun does not ſhine ſo bright as to give a ſhadow, you can ſet the braſs circle in a line with his body, if he is at all viſible, by your eye. The principal advantage at firſt aimed at in this compaſs was, to contrive a dipping-needle, which ſhould be ſufficient for making obſervations at ſea; as thoſe needles, to be of uſe, muſt be placed, by ſome means or other, in ſuch a manner, as that all their vibrations ſhall be made in the true magnetic meridian, north and ſouth, otherwiſe they are good for nothing. For, if one of them is placed, at right angles, acroſs the magnetic line, it will ſtand perpendicularly up and down, in any part of the world; the leaſt dip, therefore, is always in this magnetic line. But the only method of ſetting a dipping-needle at ſea, has hitherto been to place it in a line with the common compaſs-needle; and this muſt be very inaccurate, if they are at any conſiderable diſtance one from the other; or, if they were near, the two needles would influence one another, and neither of them could be true: nay, ſuppoſing them for once to be properly placed in this line, the leaſt motion of the ſhip throws them out again. But this inſtrument has a conſtant power in itſelf, not only of ſetting itſelf in the proper poſition, but alſo of keeping itſelf ſo; or of reſtoring itſelf to the ſame ſituation, if at any time it had loſt it; and it is curious to ſee how, by its double motion, it counteracts, as it were, the rolling motion of the veſſel. I have only one thing farther to obſerve, that, as it is impoſſible for human hands to make any inſtrument mathematically true, ſo, when we have two graduations to look to, as in the preſent caſe, one on the north, and the other on the ſouth end of the needle, we ought to attend to both, and take the medium for the true dip or variation, pretty nearly. But in this compaſs, there is another method of examining the obſervations. Take a good artificial magnet, and on the outſide of the compaſs-box point one end of it towards the needle, and, by moving your magnet, you may thus guide the north end of the needle round the ſouth, or *vice verſâ*, without opening your compaſs-box. The magnet being then laid aſide, the needle will come to its true poſition, after a few vibrations: but, as both the needle and the circle of inclination are now reverſed, (Dr. Lorimer means that the magnet ſhould be applied in ſuch manner as to turn the parallelogram and circle of inclination half way round horizontally; ſo that, that end of the axis of the needle, which before pointed to the weſt, ſhall now point to the eaſt,) it will not point exactly to the ſame diviſion as before; yet, a mean of the two will be the truth, as nearly, I believe, as it is poſſible for any inſtrument to give it.

"Query 1ſt. May not a part of this ſmall difference be attributed to the direction of the magnetic influence, whatever that be, in the ſteel bar? and, if ſuch an experiment could be tried upon the preſent azimuth compaſſes, is it not probable, that the variation in them would be at leaſt as ſenſible? Query 2d. May not this be the cauſe that two of the beſt of them will differ a ſmall matter from one another? Query 3d. Would the ends of the needle being made angular, inſtead of the ſquare form, be, in ſome meaſure, a remedy for this ſmall variation? I am, &c."

N. B. This inſtrument requires a moſt exquiſite workmanſhip;

manſhip; and the ſockets wherein the pivots move ought to be made of agate.

The only thing which remains to be added for the completion of this article, is a ſtatement of ſome of the beſt obſervations that have been made with the dipping needle; reſpecting this, however, our ſtatement will be very ſhort, conſidering that little dependence can be placed upon moſt of theſe obſervations, eſpecially thoſe that have been made at ſea. In general it may be obſerved with reſpect to the dipping needle in different parts of the world; 1ſt. that its inclination does not alter regularly in going from north to ſouth, or *vice verſâ*, along any meridian; and 2dly, that the variation of the dip at the ſame place, but at different times, is very ſmall.

In London, the dip, as obſerved by Norman, (the inventor of the dipping needle,) in 1576, was 71° 50′. In 1676 it it was 73° 47′ according to Mr. Bond. In 1720 Mr. Whiſton made it 75° 10′. In 1723 Mr. Graham found it to be 73½° or 75°. In 1775 Mr. Cavendiſh made it 72° 30′.

A great many other obſervations made with the dipping needle may be found in the accounts of voyages, tranſactions of learned ſocieties, &c.

DIPPO, in *Ancient Geography*, a town of Spain, marked in Antonine's Itinerary, between Cordoua and Merida.

DIPPOLDISWALDA, in *Geography*, a ſmall town of Saxony, in the circle of Miſnia, ſituated 10 miles ſouth of Dreſden, towards Bohemia, with a population of 1200 individuals, whoſe principal trade conſiſts in hewing excellent

mill and whet-ſtones, out of the neighbouring quarries. Their cutlery and potters' ware is alſo much praiſed.

Near Dippoldiſwalda is the tomb of a Tartar, called Muſtapha Sulkiwicz, who, in the ſeven years war, fell as the firſt lieutenant in a Saxon regiment of Coſſacks. It was erected in the year 1762, but time had conſiderably injured it, when the Pruſſians, againſt whom he had fought, but who honoured his valour, reſtored it in 1778.

DIPSACEÆ, in *Botany*, the 56th natural order in Juſſieu's ſyſtem, or the firſt of his eleventh claſs. The definition of this claſs is, *cotyledons*. 2 *Flowers* monopetalous, ſuperior. *Anthers* diſtinct. Proper *calyx*, or *perianth* ſuperior, of one leaf. *Corolla* of one petal, very rarely of many petals cohering by a broad baſe, ſuperior, or placed upon the piſtil, often regular. *Stamens* of a definite number, their filaments inſerted into the corolla, their anthers ſeparate. *Germen* ſimple, inferior; ſtyle often ſingle, ſometimes manifold, or elſe wanting; ſtigma ſimple or divided. *Seed* inferior, or rather, for the moſt part, the fruit is capſular or pulpy, of one or many cells, and containing one or many ſeeds.

The characters of the order of *Dipſaceæ* are, *Calyx* ſimple or double. *Corolla* tubular, with a divided limb. *Stamens* of a definite number. *Style* one; ſtigma ſimple. *Capſule* for the moſt part containing a ſingle ſeed, and not burſting, having the aſpect of a naked ſeed; very rarely it has two or three cells, with a ſeed in each. *Embryo* without a ſeparate albumen, its radicle ſuperior. *Stem* in general herbaceous. *Leaves* oppoſite, rarely whorled. *Flowers* in a few inſtances diſtinct, in general aggregate upon a common chaffy receptacle, within a common calyx of many leaves. The firſt ſection compoſed of aggregate flowers, contains *Morina*, *Dipſacus*, *Scabioſa*, *Knautia*, and *Allionia*; the ſecond ſection, deſtined for diſtinct flowers, only *Valeriana*. Juſſieu, in a learned paper, on the New Holland genus, *Opercularia*, in the 4th vol. of the Annales du Muſeum, 418, conſiders it as forming a new natural order between the *Dipſaceæ* and *Rubiaceæ*, to which the *Valeriana*, and Adanſon's *Fedia*, (*Valeriana Locuſta*, &c. of Linn.) ſhould be removed. Ventenat remarks, Tabl. du regne végétal, v. 2, 556, that Adanſon was the firſt botaniſt who detected the eſſential diſtinctions of the order *Dipſaceæ*. We are at a loſs to account for Juſſieu's referring the *Morina* to the ſection of aggregate flowers, with which it accords in no other reſpect than having a double calyx. See Flora Græca Sibthorpiana, t. 28. The inflorescence is truly whorled, and each flower has its ſeparate ſtalk.

DIPSACUS, ſo called by Pliny after Theophraſtus, from διψαω, to be thirſty, (alluding to the baſins formed by its leaves for holding water, in which birds and other ſmall animals may ſlake their thirſt,) Teaſel, or Venus's Baſin. Linn. Gen. 48. Schreb. 64. Willd. Sp. Pl. v. 1. 543. Juſſ. 194. Gærtn. t. 86. Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Aggregatæ*, Linn. *Dipſaceæ*, Juſſ.

Gen. Ch. *Cal.* Common Perianth of many leaves, containing many flowers; its leaflets longer than the flowers, lax, permanent; Proper Perianth ſmall, ſuperior, of one leaf. *Cor.* the univerſal one regular; proper one monopetalous, tubular; its limb four-cleft, erect, the outer ſegment largeſt and ſharpeſt. *Stam.* Filaments four, capillary, longer than the corolla, and inſerted into its tube; anthers incumbent. *Piſt.* Germen inferior; ſtyle thread-ſhaped, the length of the corolla; ſtigma ſimple. *Peric.* none. *Seeds* ſolitary, columnar, crowned with the partial calyx. *Common receptacle* conical, beſet with long chaffy ſcales between the flowers.

Eſſ. Ch. Common calyx of many leaves; perianth ſuperior,

rior, of one leaf. Receptacle chaffy. Seed-crown cup-ſhaped.

D. *fullonum*, the Manured Teaſel, is the moſt important ſpecies, on account of its uſe in dreſſing woollen cloth. Hence it is called *Carduus fullonum*, or Fuller's Thiſtle. See Lobel's Icones v. 2. 17, and Gerarde's Herbal 1167. (Dipſacus ſativus.) The leaves are united at the baſe, and ſerrated. Scales of the receptacle reflexed or hooked, whence its uſe in preference to *D. ſylveſtris*, *Engl. Bot.* t. 1032, whoſe ſcales are ſtraight and much ſofter. This laſt grows wild in many parts of England, the former is ſcarcely found but in a cultivated ſtate. For its culture and uſe, ſee TEASEL.

DIPSACUS, in *Medicine*, according to ſome, is the ſame with a diabetes.

DIPSAS, in *Zoology*, a ſort of ſerpent, the biting of which has been ſaid to produce ſuch a thirſt as proves mortal; whence it is called *dipſas*, which in Greek ſignifies *thirſty*. In Latin it is called *ſitula*, a pail. Moſes ſpeaks of it in Deut. viii. 15.

The Hebrew word *tzimaon* anſwers very well to the Greek dipſas, and expreſſes the thirſt occaſioned by the biting of this ſerpent. Some by the Hebrew *tzimaon* underſtand a deſart or dry place. The dipſas in the Linnæan Syſtem is a ſpecies of *Coluber*; the green coluber, with ten white lines of Boddaert, and the cærulean Surinam ſerpent of Seba. See COLUBER.

DIPTERA, in *Entomology*, the ſixth order in the Linnæan Syſtem. The inſects of this order are known by having two wings, with a clavated poiſer under each, as in the common houſe fly (muſca domeſtica) which is of this kind. See article ENTOMOLOGY.

DIPTERE, or DIPTERON, in the *Ancient Architecture*, a temple ſurrounded with a double row of columns, which form a ſort of porticos, called wings, or iſles.

The word is Greek, formed from δις, *twice;* and πτερον, *ala*, *wing*.

DIPTERYX, in *Botany*, (from δις, double, and πτερον, a wing, becauſe the two upper ſegments of the calyx reſemble a pair of wings,) Schreb. 485. Willd. Sp. Pl. v. 3. 910. Mart. Mill. Dict. v. 2. (Coumarouna; Aubl. Guian. t. 296. Juſſ. 364. Baryoſma; Gærtn. t. 93.) See COUMAROUNA. To this is juſtly added, by Schreber, Taralea of Aublet, t. 298, under the following characters. Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch.. *Cal.* Perianth top-ſhaped, of one leaf; its two upper ſegments oblong, concave, ſpreading like wings; the lower one ſmall, entire or three-toothed. *Cor.* Papilionaceous. Standard longeſt, obovate, erect, with inflexed ſides. Wings two, oblong, ſhorter. Keel ſtill ſhorter, of two petals. *Stam.* Filaments eight or ten, united into a tube cloven at the upper ſide; anthers ſmall, roundiſh. *Piſt.* Germen ſtalked, oblong; ſtyle awl-ſhaped, aſcending; ſtigma acute. *Peric.* Legume large, ovate, compreſſed, thick, of one cell. *Seed* one, ovate.

Obſ. Coumarouna of Aublet has eight ſtamens, and the lower lip of the calyx undivided; Taralea ten ſtamens, and the lower lip of the calyx three-toothed. The two plants are ſo much alike in habit and fructification, that it is truly wonderful any botaniſt could ſeparate them, and yet by ſome ſtrange accident they have fallen aſunder even into two different ſections of Juſſieu's *Leguminoſæ*, p. 450 and 364.

Eſſ. Ch. Calyx with its two upper ſegments dilated, ſpreading like wings. Stamens all connected. Legume coriaceous, of two valves and one cell. Seed ſolitary.

1. D. *odorata*. Willd. Sp. Pl. v 3 910. "Leaves alternate. Cluſter terminal." Of this an account has already been given under the article COUMAROUNA. The ſeeds are now frequently ſold in the tobacconiſts' ſhops of London, by the name of Tongo Beans, and are uſed to give a flavour to ſnuff. Their ſcent is like that of new hay, or the dried herb Woodruff, *Aſperula odorata*. Gærtner having only ſeen a half ripe fruit, in which ſtate it appears uſually to be gathered for a perfume, miſtook it for a *drupa*, but Aublet, who ſaw it growing, expreſsly deſcribes it as a legume of two valves.

2. D. *oppoſitifolia*. Willd. Sp. Pl. v. 3. 910. Mart. Mill. Dict. v. 2. (Taralea oppoſitifolia; Aubl. Guian. v. 2. 745. t. 298.) "Leaves oppoſite. Flowers panicled." A native of the vaſt foreſts of Guiana, about large rivers, flowering in October, and ripening fruit in March. This is a tree 60 feet high, and 2½ in diameter. The outer bark ſcales off in large membranous flakes. The wood is white, hard, compact, and heavy. *Branches* long and widely ſpreading. *Leaves* oppoſite, croſſing each other in pairs, pinnate, of four or five pairs of ſmooth, oval, pointed, large leaflets. *Panicles* terminal, large, ſubdivided in an oppoſite manner. *Flowers* violet-coloured, exhaling a pleaſant ſcent, which is perceptible at a conſiderable diſtance.

DIPTOTES, from δις, and πτωτος, of πιπτω, *cado*, in *Grammar*, a kind of irregular nouns, having only two caſes; as *fors*, *forte*.

DIPTYCHA, in *Antiquity*, a public regiſter, wherein were written the names of the conſuls, and other magiſtrates, among the heathens; and of biſhops, and defunct as well as ſurviving brethren, among the Chriſtians.

The word diptycha is formed from the Greek διπτυχον, of διπτυχα, and that from διπτυξ, a maſculine noun, derived from πτυσσω, *I fold*, or *plait*. From its future πτυξω, is formed πτυξ, a *fold*, or *plait*. to which adding δις, *twice*, we have διπτυξ, in the genitive διπτυχος, whence the nominative neuter, διπτυχον, q. d. *a book folded in two leaves*; though there were ſome in three, and others in four or five leaves. An ingenious author imagines this name to have been firſt given them to diſtinguiſh them from the books that were rolled, called volumina. See VOLUME and BOOK.

It is certain there were profane diptycha in the Greek empire, as well as ſacred ones in the Greek church. The former were the matricula, or regiſter, wherein the names of the magiſtrates were entered; in which ſenſe diptycha is a term in the Greek chancery.

DIPTYCHA, *ſacred*. The word is plural; diptycha being a double catalogue, in one whereof were written the names of the living, and in the other thoſe of the dead, which were to be rehearſed during the office. We meet with ſomething not unlike the ſacred diptychs of the Greeks, in the canon of the maſs, according to the Latin uſage; where the people are enjoined to pray once for the living, and once for the dead; ſeveral ſaints are invoked in different times, &c.

In theſe diptycha were entered the names of biſhops, who had governed their flocks aright; and theſe were never expunged out of the ſame, unleſs they were convicted of hereſy, or ſome other groſs crime. In the diptycha were likewiſe entered the names of ſuch as had done any ſignal ſervice to the church, whether they were living or dead, and mention was made of them in the celebration of the liturgy.

There were two ſorts of theſe diptycha; the firſt contained the names of the patriarchs, popes, and biſhops, who preſided over the largeſt churches, and were ſtill alive: in the other were written the names of thoſe who died in the peace and communion of the church. The deacon uſed to

read thoſe names at the altar during divine ſervice. As the admiſſion of any biſhop's name into theſe public tables was a token and pledge of communion, ſo the eraſure of any one's name out of them was a denial of communion with him, and a kind of excommunication. The uſe of theſe diptychs is very ancient, and can be traced up to the fourth century at leaſt, if not higher. They contained, ſometimes, beſides the names of biſhops, thoſe alſo of other men, famous for their holineſs and piety, and eſpecially thoſe of the orthodox emperors, nay, even of general councils; as appears by the emperor Juſtinian's letter to Epiphanius, patriarch of Conſtantinople. Theſe diptychs are often mentioned by the fathers, councils, and eccleſiaſtical hiſtorians.

Caſaubon, in his obſervations on Athenæus, lib. vi. cap. 14, ſuppoſes the Chriſtians to have borrowed the cuſtom of writing names in a book, and rehearſing them at maſs, from the heathens, who entered the names of perſons they would do any ſignal honour to, in the verſes of the Salii; as was done Germanicus and Verus, ſons of the emperor Marcus Aurelius, and a long time before, during the age of the republic, to Mamurcus Veturius, and Lucia Volumnia, as we are told by Tacitus, lib. ii. Spartian, Ovid, Feſtus, Plutarch, &c. But Fa. Roſweyd does not approve this notion of Caſaubon. The pretended St. Dionyſius, a very ancient author, ſays the contrary, and aſſerts the firſt eſtabliſhment of this uſage to have been founded on ſcripture, 2 Tim. ii. 19. Pſalm cxvi. 15. Roſweyd adds Eccleſiaſtic. xliv. 1. and takes theſe to have been the paſſages the ancient church had a view to, rather than the Salian verſes.

The profane diptycha were frequently ſent as preſents to princes, &c. on which occaſion they were finely gilt, and embelliſhed; as appears from Symmachus, lib. ii. ep. 81. Thoſe preſented were uſually of ivory. The firſt law, De Expenſ. Ludor. C. Theod. forbids all magiſtrates below conſuls to make preſents of diptycha of ivory in the public ceremonies.

DIPUS, in *Zoology*, a genus of quadrupeds, much reſembling the dormouſe: their hind feet are long, and enable them to make prodigious bounds, and with their fore paws they carry food to their mouths like the ſquirrel. They are generically diſtinguiſhed by having two fore teeth in each jaw: the fore legs very ſhort, the poſterior ones long, and the tail long and tufted at the tip.

Species.

Sagitta. Hind feet three-toed: no thumb claw. Schreber. *Mus Sagitta: cauda longiſſima apice ſubpennata nigro-alba, pedibus poſticis longiſſimis tridactylis*, Pallas.

There appears to be two varieties of this animal; or at leaſt two ſpecies ſo cloſely allied, as to leave us in conſiderable doubt whether they ought to be conſidered as varieties, or ſpecies. The firſt, called by Schreber *ſagitta*, as abovementioned, has three toes on the poſterior feet, and no thumb claw. The head of this is rounded, the ears longer than the head, the toes hairy, and the tail terminating in a tuft. The other, *Ægyptius*, has alſo the poſterior feet three-toed, but has a claw on the fore thumb: the body of this kind is thin, and flattened at the ſides; the hair on the head and upper parts of the body long, and ſoft, and of a tawny colour; the breaſt and belly whitiſh, with a duſky band acroſs the upper parts of the thighs. Both inhabit the eaſt, and have the ſame manners, living in ſandy plains; but the firſt is ſaid to extend towards Siberia, the other to be confined to Egypt and Barbary.

The ſpecies *ſagitta* is ſuppoſed to be the μυς δίπους, or *two-footed mouſe*, of the ancients, an animal repreſented on the coins of Cyrene, where it was anciently found in great abundance; and which place it ſtill inhabits. In the Journal de Phyſique for November 1789, Sonnini laid before the public an intereſting account of this jerboa, which animal he had full opportunity of examining during his travels in that part of the globe. "It is in the burning climate of Africa principally (ſays this writer) that nature ſeems to have taken pleaſure in varying, in a manner altogether ſingular, the forms of the beings which ſhe has placed there, and in deviating from the rules and the proportions which ſhe ſeemed to have adopted, if, however, that can be called a deviation which is a proof of her boundleſs and inexhauſtible fecundity. On that fiery ſoil it is we find the giraffe, or cameleopard, remarkable for the diſproportionate height of his fore legs. We likewiſe find an extreme diſproportion between the legs of the jerboa; but the hinder legs are, in this animal, exceſſively long, while the fore legs ſcarcely appear. Theſe long limbs, or to expreſs myſelf with greater preciſion, theſe long feet, for it is the tarſus which is ſo immoderately lengthened, are of uſe to the jerboa only in his progreſſive movement: thoſe before, which may be conſidered as little hands, are uſeleſs to him in removing from place to place. He hops after the manner of birds, and this kind of motion, which would be very conſtrained to any other quadruped, is ſo much adapted to him, that his running, or rather his leaping, is very nimble, and very ſpeedy."

"The ſize of the jerboa is nearly that of a large rat; the head is broad, large in proportion to the body, flattened above, and of a clear pale red, with a blackiſh ſhade; the upper jaw projecting beyond the lower, and both furniſhed with two inciſive teeth; thoſe above are broad, cut in right angles, flat, and divided lengthwiſe, by a groove paſſing through the middle; thoſe of the under jaw are longer, convex externally, pointed at their extremity, and bent back inwardly. It is evident that theſe teeth are diſpoſed nearly as thoſe in the hare, the rabbit, and field mouſe, and this reſemblance has procured all theſe names to the jerboa. It would have been juſt as reaſonable to take him for a beaver or porcupine. The ſnout is ſhort, broad, and obtuſe; a number of ſtiff hairs extend from ſide to ſide, and form long whiſkers. The noſe is naked, wide, and cartilaginous; the eyes large, and prominent, with brown irides; the ears long, large, and covered with ſhort hair; externally theſe are white in the lower part, and grey upwards; the middle, as well as the ſides of the head, is of a very light fawn colour, mixed with grey and black; they entirely ſurround the meatus auditorius for about a third of their length, ſo that they exactly reſemble the larger end of a cone, a conformation that muſt increaſe the animal's faculty of hearing, and which is particularly well calculated to defend the inner part of the organ from the extraneous ſubſtances that might otherwiſe find admiſſion.

"The body is broader behind than before, and well covered with long, ſoft, and ſilky hair; that on the back and ſides aſh-colour, almoſt the whole length through, and of a clear fawn-colour, where it approaches the points, which are black; but as the aſhy part is not apparent, it may be ſaid the fur is fawn-coloured, with blackiſh zig-zag ſtripes. Theſe tints, which are ſomewhat duſky, form an agreeable contraſt with the fine white of the belly. The fore legs are ſo ſhort, that they ſcarcely extend beyond the hair; they are white, and have five toes, the greateſt of which, or interior toe, is very ſhort, rounded at the extremity, and has no nail; the other four, the ſecond whereof, outwardly, is the longeſt, are of conſiderable length, and armed with great hooked-nails. The heel is very much raiſed, and the inſide, or ſole of the feet, is fleſh-coloured. The hind legs are covered with long hair, of a fawn colour, and white; its

long

long feet are almoſt entirely bare, eſpecially on the outſide, which muſt neceſſarily be the caſe, ſince the animal, whether in motion or at reſt, conſtantly leans on that part. Theſe feet, ſo exceedingly long, have each three toes, the middle one of which is rather longer than the other two; they are all provided with nails, which are ſhort, but broad and obtuſe, and they have alſo a kind of ſpur, or rather a very ſmall rudiment of a fourth toe, which conſtitutes a point of reſemblance between the jerboa of Egypt, and the alagtaga of Tartary." According to Haſſelquitz, the tail of the jerboa is three times the length of the body; but Sonnini obſerves, that he never ſaw the tail above half this length. Its circumference is not much exceeding that of a large gooſe-quill, and is of a quadrangular form; its colour grey, deepeſt above, and covered with ſleek hair down to the extremity, which terminates in a tuft of long ſilky hair, half black and half grey.

On comparing this deſcription with that which Gmelin has given of the alagtaga, in the new commentaries of the academy of Peterſburgh, ſays Sonnini, it will appear that the jerboa has a ſtrong reſemblance to it: they have both the ſame number of toes on the fore-feet, the ſpur on the hinder, and the ſame length of tail, which is a proof of two things; firſt, that the jerboa and the alagtaga are one and the ſame animal; and, ſecondly, that the deſcriptions which have been given of the jerboa are not very accurate. What chiefly ſuggeſted doubts to Buffon's mind reſpecting the identity of the jerboa and alagtaga, was the diſparity of the climates which each inhabited, the former being reſident in Africa, and the alagtaga being found in the cold regions of Siberia. But this is not the only inſtance which might be adduced to the ſame effect. Many ſpecies of animals are equally ſcattered over the icy countries of the north, and over the ſultry diſtricts of the ſouth. Rats take pleaſure to reſide in very hot climates, and they live very comfortably in the north of Sweden. Hares inhabit with equal convenience, the ſnows of Lapland, of Siberia, and Greenland. It is certain that the gerboiſe of Cyrenaïs, or the deſerts of Barca, deſcribed by Mr. Bruce, in his Travels in Nubia and Abyſſinia, is only a variety in the tribe of the jerboa. The ſlight differences remarked not being, by far, ſufficient to conſtitute two diſtinct ſpecies. To the researches of Mr. Bruce we are further indebted for the exact knowledge of another animal, which had, very improperly, been confounded with the jerboa, and to which he has given the name of *daman-iſraël*, or lamb of Iſraël. So far from having the diſtinctive character of the jerboa, this daman has all his legs equal, or nearly ſo, and he has no tail; whereas, that of the jerboa is very long. Dr. Shaw, the traveller through Barbary, was the firſt who fell into the miſtake of confounding two animals ſo very unlike; and this error was ſucceſſively copied till Mr. Bruce detected it, whoſe obſervations have thrown much light on a ſubject formerly involved in doubt and darkneſs. By taking the jerboa for the daman-iſraël, the ſame which the Hebrews call ſchaſan, all that Arabian authors have ſaid of the ſecond has been aſcribed to the firſt.

The jerboa meaſures from the tip of the noſe to the origin of the tail five inches and a half, the tail itſelf eight inches and a half, and the total length of the poſterior legs about ſix inches. There is ſcarcely any difference in the ſize of the two ſexes. The females have eight nipples, the poſition of which is remarkable; they are ſituated more externally than in other quadrupeds; the firſt pair is beyond the bend of the ſhoulders, and the laſt is rather under the thigh than the belly; the two other pairs, being on the ſame line, are conſequently placed rather under the flanks than under the body.

The jerboa is commonly found in Lower Egypt, principally in the Bahiré, or weſtern part. The denomination of rats or mice of the mountain has been improperly applied to them, for all the lower part of Egypt is a plain. The ſands and rubbiſh which ſurround modern Alexandria are very much frequented by the jerboa. They live there in troops, and with their nails and teeth dig a habitation for themſelves in the ground, and can even penetrate through the ſoftiſh ſtone which is under the layer of ſand. Without being actually wild, they are exceedingly reſtleſs; the ſlighteſt noiſe, or any new object whatever, makes them retire to their holes with the utmoſt precipitation. It is impoſſible to kill them, except by ſurprize. The Arabs contrive to take them alive, by ſtopping up all the avenues to their burrows except one, by which they force them to come out. Their fleſh is not eſteemed a delicacy, though it is eaten; their ſkin, which is ſoft and ſhining, is uſed as a common fur.

M. Sonnini fed for ſome time, while in Egypt, ſix of theſe animals in a large cage of iron wire. The firſt night they had entirely gnawed aſunder the upright and croſs ſticks of their priſon, and he was under the neceſſity of having the inſide of the cage lined with tin. They lived on wheat, rice, nuts, and every ſpecies of fruit. They were very fond of baſking in the ſun, and the moment they were put into the ſhade they clung cloſe to each other, and ſeemed to ſuffer from the privation of warmth. It has been affirmed that the jerboa ſleeps by day, and never in the night time; M. Sonnini obſerved preciſely the contrary. In a ſtate of liberty they are met with in broad day light gathering round their ſubterraneous habitations, and thoſe which he fed himſelf were never more lively, nor more awake, than when expoſed to the full blaze of the ſun. Though they have much agility in their movements, gentleneſs and tranquillity ſeem to form their character. They ſuffered themſelves to be ſtroked with great compoſure; and there was among them neither noiſe nor quarrel, even when food was ſcattered among them. They teſtified no ſymptoms of joy, or fear, or gratitude; their gentleneſs was by no means amiable, or intereſting; it appeared to be the effect of a cold and complete indifference approaching to ſtupidity.

According to the remarks of M. Berthout-van-Berchem, (ſecretary to the Society of Phyſics,) publiſhed in 1788, the jerboa and alagtaga are two diſtinct ſpecies. The jerboa, he obſerves, of which Mr. Pennant ſpeaks, under the name of alagtaga, and which ought to have been written alak-daaga, has five toes on the hinder feet; the ſecond has only three, and differs from it likewiſe in ſeveral other characters. "In order to diſtinguiſh," ſays he, "this firſt ſpecies, which M. Pallas denominates *mus jaculus*, I ſhall call it *jalma*, from the name given to it by the Calmucks, and ſhall preſerve to the ſecond ſpecies the name of jerbo or jerboa. M. Pallas has obſerved three varieties in the jalma, which appear to differ principally in the ſize. The moſt common, which is of the middle ſize between the other two, is the jalma or alak-daaga. It is often found in eaſtern Tartary, in the deſerts of Siberia, and in the regions beyond the Baïkal. It is likewiſe found in Syria, nay even ſo far as India. Mr. Pennant ſays, it is met with in Barbary: but there is no authentic evidence that the jalma is an inhabitant of Africa. He even remarks that it prefers colder countries than what ſuit the jerboa, an inhabitant of warm climates. The ſecond variety is the largeſt of either; it is more rare than the firſt; they give it the name of marine

jalma,

jalma, and it is to be found in the graſſy hills of the Tanaïs, of the Volga, of the Rhymnus, and the Irtis. It is to this variety that we are to refer the animal which Dr. Shaw has erroneouſly deſcribed under the name of *daman iſraël*, and which is the ſize of the rabbit. The third variety is found, with the large one, towards ſalt meridional marſhes of the Caſpian ſea, and with the middle ſized one, in the vicinity of the Volga, and of the Rhymnus. They give it the name of choin-jalma; it is the ſmalleſt of the three. The largeſt, or marine jalma, is the ſize of a ſquirrel; the middle-ſized, or jalma, is about as big as a rat, and the ſmalleſt ſcarcely ſo large as a field-mouſe. All theſe families have five toes on the hinder foot; and in the great number which M. Pallas examined, he never ſaw a ſingle variation as to the number of toes. But what has led Buffon and Sonnini into an error, is the faulty deſcription given by Gmelin, who never ſaw but a ſingle ſpecimen, probably disfigured, and which preſented to him only three toes, and a ſpur, or four toes. He is likewiſe miſtaken with reſpect to the manners of this animal, in aſcribing to it thoſe of the *lepus ogotona*; an error which has been ſince copied by the younger Gmelin. Meſſer-Chmidt, who had left a good deſcription of this animal, does not pretend to ſay that it had only four toes. It muſt be admitted then, that this ſpecies is entirely diſtinct from the other, which has three toes on the hiuder foot."

The Egyptian jerboa appears to be well diſtinguiſhed from the Siberian kind, by having only three toes on the poſterior feet inſtead of five. Both ſpecies are ſubject to varieties, both in ſize and colour, and alſo in their general habits of life.

Jaculus. Tail, very long, with ſubpennated black and white tip: poſterior legs large and five clawed. Pallas. *Alagtaga*, Schreber. *Siberian Jerboa*, Penn.

This agrees in appearance with the Egyptian Jerboa, but grows to a larger ſize: it is diſtinguiſhed principally by the remarkable character of the hind feet, each of which has a pair of very conſpicuous ſpurs, or additional toes ſituated at ſome diſtance above the front toes, and which are furniſhed with ſharp claws.

The colour of the Siberian jerboa or alagtaga is nearly the ſame as that of the Egyptian, but has no appearance of a duſky band acroſs the lower part of the back, or any tranſverſe undulations, the whole upper parts being of a pale yellowiſh fawn colour, and the under parts white. The length of the body is about eight inches, and of the tail ten. According to Dr. Pallas it is found from the Caſpian ſea to the Irtiſh, but is no where very frequent. It inhabits dry and ſandy ſoils. There are apparently two varieties of this ſpecies differing a little in ſize and colour, but not ſufficiently to conſtitute two ſpecies. The firſt is the middle Siberian jerboa which is the ſize of a rat, and has the thigh croſſed by a white line, and a whitiſh zone or circle ſurrounding the noſe; the other is the pigmy Siberian jerboa which reſembles the former but has no white circle round the noſe, and has a ſmaller tuft to the tail, and is tipped with white; its ſize is much inferior. Both inhabit the ſame countries, and agree in their habits of life, burrowing in hard clayey ground, not only in high and dry ſpots, but even in low and ſalt places. They dig holes with their fore feet and teeth forming oblique and winding burrows of ſome yards in length, and ending in a large hole or neſt, in which a ſtore of proviſion, conſiſting of herbs, is preſerved. They are ſaid to wander about chiefly by night, and to ſleep rolled up with the head between the thighs: they are extremely nimble, and on the approach of danger ſpring forward ſo ſwiftly that a man well mounted can ſcarcely overtake them. Theſe animals are ſaid to be particularly fond of the roots of tulips and other bulbous plants, and that during the winter, they ſleep in the manner of dormice.

Mr. Bruce is believed to allude to this ſpecies, when ſpeaking of the Arabs of the kingdom of Tripoli making good diverſion with the jerboa, in training their grey-hounds which they employ in hunting the gazel or antelope. The prince of Tunis, ſon of Sidi Youngis, and grandſon of Ali Bey, who had been ſtrangled by the Algerines, when that capital was taken, being then an exile at Algiers, made a preſent to Mr. Bruce of a ſmall grey-hound, which often gave him excellent ſport. "It may perhaps be imagined (ſays Mr. Bruce) that a chaſe between theſe two creatures could not be long: yet I have often ſeen, in a large incloſure or court-yard, the grey-hound employ a quarter of an hour before he could maſter his nimble adverſary: the ſmall ſize of the creature aſſiſted him much; and had not the grey-hound been a practiſed one, and made uſe of his feet as well as teeth, he might have killed two antelopes in the time he could have killed one jerboa."

Cafer. Ferruginous above, beneath pale-aſh: anterior feet five-toed, poſterior four: tail villoſe with black tip. *Palmis pentadactylis, plantis tetradactylis*, Schreber. *Jerboa capenſis*, Forſter. *Cape Jerboa*, Pennant.

The largeſt of the genus, and inhabits the mountainous country to the north of the Cape of Good Hope. Its length from the noſe to the tip of the tail near fifteen inches. The head is broad; the muzzle ſomewhat ſharp; and the upper jaw longer than the lower. The general colour of the animal is pale ferruginous above and pale aſh-colour beneath. The noſe is black, and bare to ſome little diſtance up the front; the ears large; whiſkers long and black; the tail is of the ſame colour with the body for half its length; the remainder blackiſh, and extremely hairy. It is an animal of great ſtrength and activity, and will ſpring to the diſtance of twenty or thirty feet at once. It burrows in the ground like the ſmaller kinds of jerboas with great care and expedition by means of its fore feet which are armed with ſtrong claws. It feeds like the ſquirrel ſeated on its haunches, and alſo ſleeps in that poſture; it makes a grunting noiſe; and is eaten by the natives. This animal is figured in the ſixth ſupplemental volume of Buffon's work. At the Cape it is known among the Dutch coloniſts by the name of *Springen Haas*, Jumping Hare.

Meridianus. Yellowiſh, beneath white: fore feet three-toed with the rudiment of another: poſterior feet five-toed: tail colour of the body. *Dipus meridianus*, Schreber. *Mus meridianus*, Pallas. *Jaculus palmis tetradactylis, plantis pentadactylis*, Erxleben. *Torrid Jerboa.*

According to profeſſor Pallas, this ſpecies was firſt figured by Seba, whoſe ſpecimen had not attained to full maturity. In 1770, Pallas received ſpecimens that were taken on the borders of the ſandy deſert of Naryn, between 46 and 47 degrees north latitude. The burrows which theſe animals formed in the dry ſoil had a triple entrance, and were about an ell deep in the ground. The ſize of the animal is between that of the common rat and field mouſe; and notwithſtanding the great length of the hind legs, it does not leap like the reſt of the jerboas, but runs in the manner of the rat tribe; and on this account Mr. Pennant places it in his diviſion of jerboid rats. The length, from the noſe to the origin of the tail, is rather more than four inches, and the tail itſelf exceeds three. The noſe is blunt, the mouth placed far beneath; the upper lip bifid; the ears large and rounded; the fore legs ſhort, with four toes, and a tubercle in place of a thumb; the hind legs long and ſlender; the exterior one

ſhorter

ſhorter than the reſt. The colour of the animal is brown above, and white beneath; the colours ſeparated along the ſides by a yellowiſh line.

TAMARICINUS. Fore feet three-toed; hind feet five-toed; tail tapering, and obſcurely annulated with brown, Schreber. Saeugth. *Mus tamaricinus*, Pallas. *Tamariſk rat*, Penn.

The length of this elegant animal is about ſix inches, meaſuring from the noſe to the tail, and the tail is nearly the ſame length; the head is oblong, with large whiſkers; the noſe blunt, with the noſtrils covered by a flap; the eyes large; ears large, oval, and naked; the ſpace round the noſe and eyes, and alſo beyond the ears, white; the ſides of the head and neck cinereous; back and ſides yellowiſh grey; breaſt and belly white; tail aſh-colour, and tinged more than half-way from the baſe with brown; the poſterior legs long in proportion to the fore legs, and the feet longitudinally black beneath; fore feet deſtitute of the thumb, but furniſhed inſtead with a warty tubercle.

This ſpecies inhabits the ſouthern parts of the Caſpian deſerts, and probably the warmer parts of Aſia; it delights in low grounds and ſalt marſhes, and burrows under the roots of the tamariſk buſhes, the fruit of which, together with the ſucculent maritime plants which it finds on the coaſts, conſtitute its principal food. Each burrow has two entrances, and is very deep; theſe animals are rarely ſeen, except in the night-time, when they quit their burrows in queſt of food.

CANADENSIS. Fore feet four-toed; poſterior five-toed; tail longer than the body, ringed, and briſtly. Jumping mouſe of Canada. Davies Mem. in Linn. Tranſ. *Canada rat*, Penn.

A ſmall ſpecies, apparently firſt deſcribed by general Davies, who had an opportunity of examining it during his reſidence in Quebec, and who has deſcribed it in the fourth volume of the Linnæan Tranſactions. The account is accompanied by drawings, repreſenting it both in its active and dormant ſtate, from two ſpecimens preſerved in the general's collection. With reſpect to the food, or mode of feeding of this animal, the general obſerves, it is not in his power to ſpeak with any degree of certainty; for though the firſt was taken alive, and lived a day and a half, it refuſed every kind of ſuſtenance, and the other was in a ſtate of torpidity when found, from which it never recovered. The firſt was taken in a large field near the falls of Montmorenci, and by its having ſtrayed too far from the ſkirts of the wood, allowed the writer, and three other gentlemen, to ſurround it, and after an hour's hard chaſe to capture it; the animal was much fatigued, and this, it is ſuppoſed, accelerated its death. During the time the animal remained in its uſual vigour, its agility was incredible for ſo ſmall a creature. It always took progreſſive leaps of from three to four, and ſometimes five yards, although ſeldom above twelve or fourteen inches from the ſurface of the graſs; but in ſhrubby places, and in woods among plants, where they chiefly reſide, they are obſerved to leap conſiderably higher. The example mentioned in a dormant ſtate was found by ſome workmen in digging the foundation for a ſummer-houſe in a gentleman's garden, within two miles of Quebec, the latter end of May. It was diſcovered incloſed in a ball of clay, about the ſize of a cricket ball, at the depth of twenty inches below the ſurface of the ground. This clayey covering was nearly an inch in thickneſs, and was broken by the ſtroke of a ſpade. It is preſumed theſe Canadian jerboas ſleep thus enveloped from the month of September till the end of May, or beginning of June following, and during that time take no ſuſtenance. The animal thus found, though preſerved in cotton, never revived; it is ſuppoſed that the heat of the apartment in which it was placed, and in which a ſtove fire was conſtantly kept burning, was too powerful for its reſpiration.

DIPYRE, in *Mineralogy*. The colour of this mineral is greyiſh or reddiſh-white, paſſing into roſe-red. It occurs either diſſeminated, or in ſmall faſcicular maſſes, or in minute priſmatic cryſtals. It has a brilliant vitreous luſtre, and a lamellar fracture parallel to the ſides of a regular hexahedron. It is moderately hard and brittle. Sp. gr. 2.63.

It is fuſible with ebullition before the blow-pipe, and is compoſed, according to Vauquelin's analyſis, of,

60	Silex.
24	Alumine.
10	Lime.
2	Water.
96	
4	Loſs.
100	

When pulverized and thrown on a hot coal, it gives a pale phoſphoric light. It occurs at Mauleon in the Pyrennées, imbedded in ſteatite.

DIPYRENON, from δὶς, and πυρὴν, a *berry*, in *Surgery*, the name of a probe, with a double button at the end, reſembling two ſmall berries growing together.

DIRACOUL, in *Geography*, a town of Aſiatic Turkey, in the Arabian Irak; 42 miles S. S. E. of Bagdad.

DIRÆ, called alſo *Deirea*, or *Deira*, a promontory and town on the ſouth-ſide of the ſtraits of Babelmandeb, in the Arabian gulf.

DIRÆ, in *Mythology*. See FURIES.

DIRCA, in *Botany*, Mouſe-wood or Leather-wood, (its derivation we are unable to explain.) Linn. Gen. 192. Schreb. 260. Willd. Sp. Pl. v. 2. 424. Mart. Mill. Dict. v. 2 Juſſ. 77. Claſs and order, *Octandria Monogynia*. Nat. Ord. *Vepreculæ*, Linn. *Thymelææ*, Juſſ.

Gen. Ch. *Cal.* none. *Cor.* monopetalous, club-ſhaped; tube ſwelling upwards; limb ſlight, with an unequal border. *Stam.* Filaments eight, capillary, unequal, inſerted into the middle of the tube, and extending beyond the border; anthers roundiſh, erect. *Piſt* Germen ſuperior, ovate, with an oblique point; ſtyle longer than the ſtamens, capillary; ſtigma ſimple. *Peric.* Drupa roundiſh. *Seed* roundiſh, ſolitary.

Eſſ. Ch. Calyx none. Corolla tubular, with a ſlight unequal limb. Stamens and ſtyle longer than the corolla. Drupa with one ſeed.

D. *paluſtris*. Linn. Amoen. Acad. v. 3. 12. t. 1. f. 7. Sp. Pl. 512. Kalm's Travels, v. 2. 148. Ait. H. Kew. v. 2. 27. Du Hamel Arb. v. 1. 211. t. 212. (Thymelæa floribus albis, primo vere erumpentibus: foliis oblongis acuminatis: viminibus et cortice valdè tenacibus, unde *Leather-wood* appellatur. Gron. Virg. ed. 1. 155.) Grows on hills bordering on ſwamps and rivers in North America, flowering in April, while the leaves are only budding. *Stem* five or ſix feet high, branched, very tough and pliant, with a ſmooth bark as tough as leather. Hence it is uſed for making ropes, baſkets, and ſimilar economical purpoſes. *Leaves* alternate, ſtalked, elliptical, entire, downy when young. *Flowers* three from each bud, pendent, on ſhort ſtalks. *Stamens* and *ſtyle* protruding far beyond the corolla.

DIRCE, in *Ancient Geography*, the name of a ſtream or fountain of Greece, in Boeotia, placed by Plutarch near Thebes,

Thebes, and ſaid by Pauſanias to diſcharge itſelf into the Hmenus. Pindar is ſaid to have had his houſe near the river Dirce.

DIRE, in *Geography*, a town of Bohemia, in the circle of Leitmeritz; 6 miles S. of Leipa.

DIREA, or DEIRA, a town of Greece, in Attica.

DIRECT, in *Arithmetic*. The rule of three direct is that oppoſite to the inverſe. See RULE *of proportion*.

DIRECT, in *Aſtronomy*. We conſider the planets in three ſtates; *viz.* direct, ſtationary, and retrograde. See PLANET.

They are ſaid to be direct, when they appear to move forward, according to the ſucceſſion of the ſigns; and retrograde, when they go the contrary way.

DIRECT, in *Matters of Genealogy*, is underſtood of the principal line, or the line of aſcendants and deſcendants; in contradiſtinction to the collateral line. See DESCENT.

A very good hiſtorian uſes the phraſe *direct* ſpeech, or harangue, when he introduces any one ſpeaking, or haranguing of himſelf: when the hiſtorian ſpeaks, and only rehearſes the chief points of what was delivered by the ſpeaker, it is called an *indirect* ſpeech.

DIRECT { *Erect* / *Eaſt* / *Weſt* } *dials*, are thoſe whoſe planes lie directly open to the eaſt, or weſt points of the heavens, or parallel to the meridian of the place. See DIAL.

DIRECT *ſouth*, or *north* { *Inclining* / *Reclining* } *dials*. See DIAL.

DIRECT, in *Muſic*, is a mark ſet at the end of a ſtaff, eſpecially at the foot of a page upon that line or ſpace where the firſt note of the next ſtaff is ſet.

DIRECT, in *Optics*. Direct viſion is that performed by direct rays; in contradiſtinction to viſion by refracted, or reflected rays. Direct viſion is the ſubject of optics, which preſcribes the laws and rules thereof. See VISION.

DIRECT *rays*, are thoſe which paſs in right lines from the luminary to the eye, without being turned out of their rectilinear direction by any intermediate body, either opaque or pellucid. See RAY.

DIRECT *ſphere*. See RIGHT *ſphere*.

DIRECTION, in *Aſtronomy*, the motion, and other phenomena, of a planet, when *direct*. See PLANET.

DIRECTION, in *Aſtrology*, is a kind of calculus, whereby they pretend to find the time wherein any notable accident ſhall befal the perſon whoſe horoſcope is drawn.

For inſtance, having eſtabliſhed the ſun, moon, or aſcendant, as maſters, or ſignificators of life; and Mars, or Saturn, as promiſers, or portenders, of death; the direction is a calculation of the time wherein the ſignificator ſhall meet the portender.

The ſignificator they likewiſe call apheta, or giver of life: and the promiſer, anereta, promiſſor, or giver of death.

They work the directions of all the principal points of the heavens, and ſtars, as the aſcendant, mid-heaven, ſun, moon, and part of fortune. The like is done for the planets, and fixed ſtars; but all differently, according to the different authors.

DIRECTION, *Iſlands of*, in *Geography*, four ſmall iſlands at the W. entrance of the ſtraits of Magellan, in the ſouth Pacific ocean. S. lat. 52° 27′. W. long. 77° 19′.—Alſo, a cluſter of iſlands on the eaſt coaſt of New Holland, three of which are within the paſſage or channel, through which Cook in 1770 paſſed into the open ſea beyond the reef, and which lies in S. lat. 14° 32′. They were ſo called, becauſe by theſe a ſtranger may find a free paſſage through the reef quite to the main. The largeſt, and the northernmoſt of the three, is called *Lizard* iſland, which ſee.

DIRECTION, *line of*, in *Gunnery*, was formerly marked on guns with a ſlit or cavity at the breech, and a button at the muzzle, ſo that they were directed in the ſame manner as fowling-pieces are; but as the platforms on which the cart carriages reſt are never laid ſo exactly level, but that one wheel is always higher than another, this line of direction muſt be falſe, and has, therefore, in modern practice, been laid aſide; and the centre-line of a piece is found every time it is fired, by a plummet, or inſtrument, which Mr. Muller complains of as a tedious and uncertain method; and he recommends reſuming the line of direction, as more expeditious, and more certain than the common practice. Syſtem of Math. vol. v. p. 90 and 230.

DIRECTION *of Motion*, in *Mechanics*, denotes the ſituation of the ſtraight line along which any particular motion is performed. Thus, let A B, (*Plate* XXII. *Mechanics*, *fig.* 3.) repreſent the two extreme points of a ſtraight line, and ſuppoſe that a body moves from A to B along that ſtraight line; then A B is ſaid to be the direction of the motion of that body. Should the body move from the point B to the point A; then B A is the direction of its motion, which is contrary to the former. The laws of motion, as explained by ſir Iſaac Newton, ſtate, that a body in motion will continue to move in a ſtraight line, unleſs it be compelled to change that direction, by a force or forces impreſſed, and independent of that which originally put it in motion. Therefore, when a body moves in a curve, it muſt be continually deflected from its ſtraight direction by the action of ſome other force, which conſtantly acts upon it; hence when a body moves in a curvilinear path, the direction of its motion is not ſaid to be that curve line; but it is ſaid that the body changes its direction at every point of its courſe, or continually. Conſequently the direction of a body ſo moving, at any particular point of its courſe, is the tangent at that particular point of the curvilinear path. In fact, if, when a body moves in a curve, the ſecondary force which acts upon it, beſides the original impulſe, ceaſes to act, then the body will fly off in the direction of the tangent at that particular point of the curve, at which the body ſtood when the ſecondary force ceaſed to act.

DIRECTION, *line of*, is a ſtraight line ſuppoſed to be drawn from the centre of gravity of that body to the centre of the earth; and if a body be left unſupported, it will fall, or move, downwards, in that direction; for ſince the momenta of all the particles of a body, that are on one ſide of its centre of gravity, are exactly equal to, or balanced by, the momenta of all the particles which are on the other ſide of that centre, it follows that the whole body muſt riſe or fall according as its centre of gravity riſes or falls: and when the body falls in conſequence of its own gravity, *viz.* in conſequence of its being attracted by the earth, the mutual forces of thoſe two bodies towards each other are concentrated in their centres of gravity; hence the body falls in the direction of the line which joins thoſe centres, or the line of direction. It will eaſily appear upon the leaſt conſideration, that the lines of direction of different bodies are not ſtrictly parallel; for they all converge towards the centre of the earth. Yet, with reſpect to any body, or ſyſtem of bodies, connected for mechanical purpoſes, the whole ſpace in which their particles are included and move is ſo very ſmall in proportion to the body of the earth, that their ſeveral lines of direction may, without any ſenſible error, be conſidered as perfectly parallel.

It is evident, from the preceding obſervations, that a body

may be ſupported by another body, when the latter is perpendicularly under the centre of gravity of the former; otherwiſe the former will fall off, or, in other words, a body will ſtand upon a baſe when its line of direction falls within that baſe, and not otherwiſe. This principle is generally and neceſſarily attended to in all movements either natural or artificial; as will be clearly illuſtrated by the following applications: A B E C, *fig.* 4, is an inclined body, ſay a block of ſtone, and H is its centre of gravity. H D is a perpendicular let fall from its centre of gravity, and of courſe is its line of direction; it being the ſtraight line which paſſes through the centre of gravity of the body and that of the earth. Now, ſince the line of direction H D falls within the baſe A C, the body will remain in that ſituation; but if an additional weight F B be laid upon it, the centre of gravity of the whole will be at I, and the line of direction I O will fall without the baſe, in conſequence of which the whole compound body A G will fall down. "Hence (Mr. Ferguſon obſerves) appears the abſurdity of people's riſing haſtily in a coach or boat when it is likely to overſet; for by that means they raiſe the centre of gravity ſo far as to endanger throwing it quite out of the baſe; and if they do, they overſet the whole effectually: whereas, had they clapt down to the bottom, they would have brought the line of direction, and conſequently the centre of gravity, farther within the baſe, and by that means might have ſaved themſelves."

This likewiſe ſhews the impropriety of building high carriages, like the very high phaetons that were in faſhion a few years ago.

If attentively conſidered, the whole motion of the body of an animal will be found to depend upon a proper regulation of the line of direction. When the line of direction falls within our feet; that is, within the baſe which is formed by our feet, we ſtand, and moſt firmly when that line falls in the very middle of that baſe; but we inſtantly begin to fall the moment in which the line of direction goes beyond that baſe. And it is curious to obſerve how nature, or our unſuſpected experience, inſtructs us in the uſe of thoſe methods and thoſe poſitions, which either maintain our neceſſary poſition, or reſtore it when loſt. When we riſe from a chair, we bend our bodies forward, by which means the line of direction falls forward beyond our feet, which obliges us to move a foot forward, in order to prevent the fall. For the ſame reaſon, a man leans forward when he carries a burthen on his back, but leans backward when he carries it on his breaſt; alſo he leans on one ſide when he carries a weight, as a pail of water, &c. on the oppoſite ſide. In walking, a man firſt extends his hindmoſt leg and foot nearly ſtraight, and at the ſame time bends the knee of his fore-leg a little; by this means his body is thruſt forward, and the line of direction from his centre of gravity falls beyond the fore-foot, on which account his fall would enſue, but he prevents it by immediately taking up the other foot, and putting it forward beyond the line of direction; after the ſame manner, he thruſts himſelf forward by extending the leg which is now the hindmoſt, till the line of direction be advanced beyond his fore-foot, when he again prevents his fall by advancing the other foot, and ſo forth.

In the ſituation of bodies of all ſorts this general principle muſt be attended to; namely, that the broader the baſe is, and the nearer the line of direction is to the middle of that baſe, the more ſteadily will a body ſtand upon it: and, on the other hand, the narrower the baſe is, and the nearer the line of direction is to the ſide of it, the more eaſily may a body be overthrown; for in this caſe the ſlighteſt change of poſition will throw the line of direction quite out of the baſe. Hence it follows, that a globular body is eaſily rolled upon a plain horizontal ſurface, and that it is extremely difficult to let an egg ſtand on one end, or any other pointed body ſtand upon its point.

We ſhall, laſtly, obſerve, that in caſe of bodies placed upon inclined planes, a body will ſlide down the plane, when its line of direction falls within its baſe, as in *fig.* 5; but the body will fall down, or roll, when its line of direction falls without its baſe, as in *fig.* 6.

DIRECTION, *Angle of*, is that comprehended between the lines of direction of two conſpiring powers.

DIRECTION, *Quantity of*, is uſed for the product of the velocity of the common centre of gravity in a ſyſtem of bodies, by the ſum of their maſſes.

In the colliſion of bodies, the quantity of direction is the ſame before and after the impulſe. Bernouilli, Diſcours ſur le Movement. Oper. tom. iii. p. 32, and 56.

DIRECTION *Chamber*, in *Commerce*. See CHAMBER.

DIRECTION, *Number of*, in *Chronology*. See NUMBER.

DIRECTING PLANE, in *Perſpective*. A plane paſſing through the eye (or point of ſight) parallel to the original plane, is called the directing plane; and the interſection of the original plane with the directing plane, is called the directing line.

There is a plane which is at the ſame time perpendicular to the original plane, to the plane of the picture, to the vaniſhing plane, and the directing plane; this is called the vertical plane, and its interſection with the directing plane is called by ſome writers the director of the eye. It is taken as the height of the eye above the original plane. The point in which the director interſects the directing line is called the ſtation point.

DIRECTIVE *Property of the Magnet*, is the power which the magnet or a magnetized body, has of placing itſelf in the magnetic line; provided it be left at liberty, or be ſo ſuſpended as to be able to move itſelf with freedom. The magnetic line in London is inclined by about 72° 30′ below the horizon, and the vertical plane of it, or through which it paſſes, cuts the horizon at an angle of about 24° from the north point of it towards the weſt. See MAGNETISM, COMPASS, and DIPPING *Needle*.

DIRECTLY, in *Geometry*; we ſay, two lines lie directly againſt each other, when they are parts of the ſame right line.

In *Mechanics*, a body is ſaid to ſtrike, or impinge directly againſt another, if it ſtrike in a right line perpendicular to the point of contact.

A ſphere, particularly, ſtrikes directly againſt another when the line of direction paſſes through both their centres. See PERCUSSION.

DIRECTOR, in *Commercial Polity*, a perſon who has the management of the affairs of a trading company: thus we ſay the directors of the India company, South-ſea company, &c. See BANK.

DIRECTORS *of Creditors*, in the *Commercial Policy of France*, are perſons of ability and property, choſen by votes of the creditors, to inſpect and examine the debtor's affairs, and to procure as far as poſſible, by common methods of juſtice, the payment of each perſon's debt. See ASSIGNEES.

DIRECTORS-*General* of the five great farms of the gabele and aids, &c. in France, are chief commiſſioners, who have the direction of theſe farms, each in the diſtricts appointed by the general farmers.

DIRECTOR, in *Surgery*, is a grooved inſtrument to conduct the ſurgeon's knife in ſeveral operations, which would otherwiſe endanger his cutting the ſubjacent parts. Directors are uſually made of ſteel or ſilver; and they vary

in ſhape, according to the form or ſtructure of the part to be operated upon. In ſome caſes the ſurgeon's finger is the beſt director. See CONDUCTOR.

DIRECTOR *Penis*, in *Anatomy*, a muſcle of the penis, called more uſually erector. See ERECTOR.

DIRECTORY *of Public Worſhip*, was drawn up by the aſſembly of divines at Weſtminſter, and eſtabliſhed by an ordinance of parliament, in 1644, repealing the ſtatutes of Edward VI. and of Elizabeth, for uniformity in the common prayer. The directory ſet aſide the uſe of the liturgy, and allowed of no church-muſic beſides that of ſinging the Pſalms.

Inſtead of one preſcribed form of prayer, the directory only points out certain topics, on which the miniſter might enlarge. The whole apocrypha was rejected; and both private baptiſm and lay baptiſm, with the uſe of god-fathers and god-mothers, and the ſign of the croſs, were diſcontinued. In the ſacrament of the Lord's ſupper, no mention is made of private communion or adminiſtering it to the ſick. The altar with rails was changed into a communion table, about which the people might ſtand or ſit; kneeling not being thought ſo proper a poſture. Lightfoot, Selden, and others were for open communion, to which the parliament alſo moſt inclined, in oppoſition to thoſe preſbyterians who were for granting powers of admiſſion or rejection to the miniſters and elders, and to the independents who were for committing them to the whole brotherhood; but it was agreed, that the miniſter, before the communion, ſhould warn, in the name of Chriſt, all ſuch as are ignorant, ſcandalous, prophane, or that live in any ſin or offence againſt their knowledge or conſcience, that they preſume not to come to that holy table, ſhewing them, that he that eateth and drinketh unworthily, eateth and drinketh judgment to himſelf. The prohibition of marriage in Lent, and the uſe of the ring, were laid aſide. In the viſitation of the ſick no mention is made of private confeſſion, or authoritative abſolution. No ſervice is appointed for the burial of the dead. All particular veſtments for prieſts or miniſters, and all ſaints-days were diſcarded. It has been remarked, as a conſiderable omiſſion, that the directory does not enjoin the reading of the apoſtles' creed, and the ten commandments. However, theſe were added to the aſſembly's confeſſion of faith, which was publiſhed a year or two afterwards. This directory continued in uſe till the reſtoration of king Charles II., when, the conſtitution being reſtored, the old liturgy took place again; the ordinance for its repeal having never obtained the royal aſſent. The revolution, thus occaſioned in the form of public worſhip, did not take place for a conſiderable time over the whole kingdom. In ſome parts of the country the church-wardens could not procure a directory; and in others they deſpiſed it, and continued the old common prayer book; ſome would read no form, and others uſed one of their own. In order to enforce the uſe of the directory, the parliament, by an ordinance, dated Auguſt 23, 1645, called in all common prayer books, and impoſed a fine upon thoſe miniſters who ſhould read any other form than that contained in the directory. Such, as Mr. Neale very juſtly obſerves, (Hiſt. of the Puritans, vol. ii. p. 109, 4to.) were the firſt fruits of preſbyterian uniformity, and they are equally to be condemned with the ſeverities and oppreſſions that had been the ſubjects of former complaints; for though it ſhould be admitted, that the parliament or legiſlature had a right to abrogate the uſe of the common prayer book in churches, was it not highly unreaſonable to forbid the reading of it in private families or cloſets? Surely the devotion of a private family could be no diſturbance to the public; nor is it any excuſe to ſay, that very few ſuffered by it, becauſe the law is ſtill the ſame, and equally injurious to the rights of mankind. By an ordinance, Auguſt 23, 1645, which continued till the reſtoration, to preach, write, or print any thing in derogation or depraving of the directory, ſubjected the offender, upon indictment, to a diſcretionary fine, not exceeding 50*l.* The king's proclamation at Oxford, dated November 13, 1645, forbidding the uſe of the new directory, and enjoining the continuance of the common prayer, was of no avail.

DIRECTORY *part of a Law*, ſtands much upon the ſame footing with the *declaratory* (which ſee); for this virtually includes the former; the declaration being uſually collected from the direction.

DIRECTRIX, in *Geometry*. See DIRIGENT.

DIRECTRIX *of the parabola*. See CONIC *Sections*.

DIRENKRUTT, in *Geography*, a town of Germany, in the archduchy of Auſtria, 5 miles S. E. of Ziſterſdorff.

DIRENOW, a river of Germany, in the circle of Upper Saxony, which runs from the Groſs Haff into the Baltic.

DIRIBITORES, among the Romans, officers appointed to diſtribute tablets to the people at the Comitia. See COMITIA.

DIRIBITORIUM, in *Roman Antiquity*, an immenſe building at Rome, which, according to Dion Caſſius, was the largeſt that was ever incloſed under one roof, and of ſuch ſize, that when it decayed by age, no perſon was able to repair it; and, therefore, it was quite open in the time of that hiſtorian. This building was begun by Agrippa, and finiſhed by Auguſtus. Its uſe has not been aſcertained; but it might probably have been intended for the accommodation of numerous aſſemblies of the people, when it would have been inconvenient, on account of heat, or cold, or rain, for them to have met together in places that were uncovered.

DIRIGENT, a term in *Geometry*, expreſſing the line of motion, along which a deſcribent line, or ſurface, is carried in the geneſis of any plane, or ſolid figure.

Thus, if the line A B (*Plate* VI. *Geometry*, *fig.* 80.) move parallel to itſelf, and along the line A C, ſo that the point A always keeps in the line A C, a parallelogram, as A B C D, will be formed, of which the ſide A B is the deſcribent, and the line A C the *dirigent*. So alſo if the ſurface A B C D be ſuppoſed to be carried along the line C E, in a poſition always parallel to itſelf in its firſt ſituation, the ſolid A D E H will be formed, where the ſurface A D is the deſcribent, and the line C E is the dirigent.

DIRIGOTHIA, in *Ancient Geography*, a town of Lower Mœſia, the ſame with Dirogetia, now *Drimago*.

DIRITTA, in the *Italian Muſic*, a term intimating that the piece is be played or ſung in conjoint degrees. Thus, contrapunto alla diritta, according to Angelo Berardi, is when one is obliged to raiſe or fall the voice by the ſame degrees, i. e. by an equal number aſcending or deſcending, without making a leap, even of the interval of a third. Broſs. Dict. Muſ. in voc.

DIRMSTEIN, in *Geography*, a town of Germany, in the circle of the Upper Rhine, and biſhopric of Worms; 7 miles S. S. W. of Worms.

DIRPHYS, in *Ancient Geography*, a mountain in the iſland of Eubœa.

DIRRITORF, in *Geography*, a town of Germany, in the archduchy of Auſtria; pillaged and deſtroyed in 1310; 3 miles N. of Steyr.

DIRSCHAU, a ſmall town of Pruſſia, on the Viſtula, ſituated in a very fertile country. It was built in 1209, and

had its own earls, when the knights of the Teutonic order invaded and conquered Pruſſia. Dirſchau is 15 miles S. of Dantzic, and ſince the peace of Tilſit forms a part of its dominions.

DIRSCHKEIM, a ſmall town of Pruſſia, in German Samland, in the diſtrict of Fiſchhauſen.

DIRT-BOAT, in *Canal-making*, &c. ſignifies a *Float*, or *flat-bottomed Boat*, generally with ſquare ends, and very ſhallow, uſed upon a canal for moving earth or other materials for the repair of the banks, &c. See CANAL.

DIRUTA, GIROLAMO, in *Biography*, organiſt of the cathedral at Chioggia in 1615, publiſhed in Italian at Venice, in fol. a book on muſic, entitled, "Il Tranſilvanſio," in dialogue between the author and his ſcholar, a prince of Tranſilvania. It contains inſtructions for playing the organ and other keyed inſtruments, with preludes by moſt of the celebrated organiſts of Italy at the time; but in theſe no keys are uſed but thoſe of the church, and all the paſſages conſiſt of running up and down the ſcale with both hands, alternately, without other intention than to exerciſe the fingers in the moſt obvious and vulgar diviſions then in uſe.

DIS, an inſeparable particle prefixed to divers words; the effect whereof is, either to give them a ſignification contrary to what the ſimple words had: as in diſgrace, diſparity, diſproportion, &c. or to intimate a ſeparation, detachment, diſtribution, &c. as in diſcerning, diſcourſing, diſtracting, diſpoſing, &c.

DISA, in *Botany*, (a name contrived by Bergius, poſſibly from Δις, *Jupiter*, to expreſs a female divinity, in alluſion to the magnificence and beauty of the flower, exceeding moſt of its tribe, and to preſerve an analogy with ſome others of that tribe, *Arethuſa*, *Cypripedium*, *Serapias*, &c.) Berg. Cap. 348. t. 4. f. 7. Linn. Suppl. 59. Schreb. 605. Willd. Sp. Pl. v. 4. 45. Juſſ. 65. Swartz. Orchid. 24. t. 1. f. B. Claſs and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*.

Gen. Ch. *Cal.* perianth of 3 leaves, generally reverſed; the two foremoſt nearly upright; the back one (which, from the uſual reverſe poſture of the flower, becomes foremoſt), nearly upright, concave or vaulted, producing from its central or bottom part, a poſterior ſpur. *Cor.* petals 2, ſmaller than the calyx-leaves, various in form, attached on each ſide to the columnar part of the ſtyle. Nectary or lip between the two foremoſt calyx-leaves, inſerted before the baſe of the ſtyle, deſtitute of a ſpur, and rarely divided. *Stam.* and *Piſt.* Germen inferior, oblong; ſtyle very ſhort; ſtigma in front, near the baſe of the ſtyle, globoſe; anther oblong, of two cells, parallel to the ſtyle, and connected with it lengthwiſe, erect or incumbent, bent back with the petals towards the ſpurred leaf of the calyx; pollen in two club-ſhaped glutinous maſſes, with a glandular baſe. *Peric.* Capſule oblong or obovate, triangular, of three valves and one cell, burſting at each angle, the top and bottom remaining entire. *Seeds* numerous, minute, roundiſh, each with a membranous tunic.

Eſſ. Ch. Calyx ſpreading, moſtly reverſed; one leaf ſpurred behind. Petals attached to the ſtyle. Lip without a ſpur. Anther parallel to the ſtyle.

Swartz enumerates 28 ſpecies of *Diſa*, all natives of the Cape of Good Hope, of which the firſt *D. grandiflora*, (*D. uniflora* of Bergius, who founded the genus,) is one of the fineſt of this natural order. Its flower is red, and elegantly veined. The maſſes of pollen are larger and more ſtriking than in any other of the *Orchideæ*. *Orchis draconis*, *biflora*, *flexuoſa*, *tenella*, *ſagittalis*, *barbata*, *tripetaloides*, *ſpatulata*, *bivalvata* and *patens* of Linnæus, are all removed by Swartz to this genus, as well as his *filicornis*, which ſeems to us ſcarcely diſtinct from the laſt.

DISABILITY, in *Law*, is when a man is made incapable to inherit lands, or take any benefit, which otherwiſe he might do, which may happen four ways; *viz.* by the act of the anceſtor; by the act of the party; by the act of law; and by the act of God.

DISABILITY *by the act of the anceſtor*, is where the man is attainted of treaſon, or felony; by which attainder his blood is corrupted, and thereby himſelf and his children are diſabled to inherit.

DISABILITY *by the act of the party himſelf*, is where a man binds himſelf by obligation, that upon the ſurrender of a leaſe, he will grant a new eſtate to the leſſee; and afterwards he grants the reverſion to another, which puts it out of his power to perform it.

DISABILITY *by the act of the law*, is when a man, by the ſole act of law, without any thing by him done, is rendered incapable of the benefit of the law: as, an alien born; ſo that if a man born out of the king's liegeance, will ſue an action, the tenant, or defendant, may ſay, he was born in ſuch a country out of the king's liegeance, and demand judgment, if he ſhall be anſwered: for the law is our birth-right, to which an alien is a ſtranger, and therefore diſabled from taking any benefit thereby.

DISABILITY *by the act of God*, is when the party is *non compos mentis*, or *non ſanæ memoriæ*, which ſo diſables him, that in all caſes where he gives, or paſſes any thing, or eſtate from him, after his death it may be annulled and avoided.

There are alſo other diſabilities by the common law, as of idiocy, infancy, and coverture, for making of grants, &c. and by ſtatute, as Papiſts are diſabled for making any preſentation to a church, &c. and officers not taking the oaths for holding offices.

DISABILITY *of the plaintiff, plea to.* See DILATORY *Pleas.*

DISABLED, in *Sea Language*, is applied to a ſhip, when, by the loſs of her maſts, yards, or rigging, or other damage, ſhe is rendered incapable of proſecuting her voyage, without great difficulty and danger.

DISABLING *a man's limbs or members*, in *Law*. See MAYHEM.

DISAFFORESTED. See DEAFFORESTED.

DISANDRA, in *Botany*, (of obſcure etymology, unleſs Linnæus meant *Dyſandra*, from δυς and ανηρ, alluding to the great uncertainty in the number of its ſtamens, and the conſequent difficulty of referring it to any of his claſſes, which induced him to place it in *Heptandria*, where it might moſt eaſily be ſeen; as was the caſe likewiſe with *Aponogeton*, Suppl. 33.) Linn. Syſt. Veg. ed. 13. 290. Suppl. 32. Schreb. 244. Willd. Sp. Pl. v. 2. 282. Mart. Mill. Dict. v. 2. Juſſ. 99. Claſs and order, *Heptandria Monogynia*. Nat. Ord. *Pedicularæ*, Juſſ.

Gen. Ch. *Cal.* Perianth bell-ſhaped, divided half-way down into from five to eight oblong, nearly ſtraight, ſegments, permanent. *Cor.* of one petal, wheel-ſhaped; tube very ſhort; limb in from five to eight deep, obovate, equal diviſions. *Stam.* Filaments five to eight, ſetaceous, ſomewhat ſpreading, equal, inſerted into the tube, ſhorter than the limb; anthers arrow-ſhaped. *Piſt.* Germen ſuperior, ovate; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma ſimple. *Peric.* Capſule ovate, the length of the calyx, of two cells. *Seeds* numerous, ovate.

Eſſ. Ch. Calyx in about ſeven diviſions. Corolla wheel-ſhaped, with about ſeven equal ſegments. Capſule ſuperior, of two cells, with many ſeeds.

D. *proſtrata*, Curt. Mag. v. 7. 218, (Sibthorpia peregrina; Linn. Sp. Pl. 880.) is the only ſpecies, a native of

Madeira, as well as of the Levant. The *ſtems* trail on the ground, or are pendent from rocks and ſtones in an elegant manner, clothed with alternate, ſtalked, kidney-ſhaped, crenate, downy *leaves*, and altogether reſembling the ſhoots of ground ivy. *Flower-ſtalks* axillary, cluſtered, ſingle-flowered, downy. *Bloſſoms* yellow. This plant is now become common in green-houſes, where it appears to advantage, as Curtis remarks, if placed on a pedeſtal, ſo that its branches may hang careleſsly down. It is eaſily propagated by cuttings, requires rich earth, and in dry weather plenty of water, bloſſoming throughout the ſummer, and indeed whenever the weather is favourable for any vegetation.

Shaw's *Chryſoſplenii foliis planta aquatica, flore flavo, pentapetalo*, Spec. Phyt. Afr. f. 149, on which Linnæus founded his *Sibthorpia africana*, Sp. Pl. 880, appears to be this very plant, not even a variety, except ſo far as the bad drawing of his figure makes it unlike nature.

DISAPPOINTMENT, in *Geography*, a bay on the N. W. coaſt of North America. N. lat. 52° 15′. W. long. 129°.

Disappointment *Iſland*, an iſland in the South ſea, ſo called by the Miſſionary voyagers in 1797, being one of the cluſter called by them "Duff's Group;" they are about 11 in number, lying in a direction S. E. and N. W. 14 or 15 miles: in the middle are two larger iſlands about ſix miles in circumference. On the N. W. ſide of the group are five or ſix more, ſome of which are high; and at the eaſt end of one of them is a remarkable rock in form of an obeliſk. The ſmall iſlands were apparently barren; but the two largeſt were entirely covered with wood, among which were ſeveral cocoa-nut trees; but, upon the whole, they exhibited no appearance of great fertility. The natives ſeemed to be ſtout and well made, with copper-coloured complexions: their houſes were built cloſe to each other, and not diſperſed, as in other places: a horde of their dwellings was ſituated on the S.W. ſide of Diſappointment iſland; in S. lat 9° 57′. E. long. 167°. Miſſ. Voyage, p. 296.

Disappointment, *Iſlands of*, a cluſter of iſlands in the South Pacific ocean, ſo called by commodore Byron in 1765, becauſe he found it impoſſible to procure at them any refreſhment for his ſick crew. The middle of this cluſter lies in S. lat. 14° 10′. W. long. 144° 52′. The variation of the compaſs was here 4° 30′ E.

DISARM, in the *Manege*. To diſarm the lips of a horſe, is to keep them ſubject, and out from above the bars, when they are ſo large as to cover them, and prevent the true preſſure or appui of the mouth, by bearing up the bit, and ſo rendering the horſe to feel the effects of it upon the bars.

Disarm. To diſarm a regiment is generally conſidered as a diſgrace, and uſually precedes its being diſembodied; becauſe, when the arms are only laid by for a while, they are ſaid to be depoſited; and when they are turned over to another corps, they are always ſuppoſed to be exchanged by the ſupply of new ones. We rarely hear of a regiment being diſarmed, except where mutiny has taken place, or that diſobedience is expected. In ſuch caſe the utmoſt precaution ſhould neceſſarily be taken; it being extremely difficult to induce ſoldiers to ſurrender their weapons; more particularly where they harbour miſchievous deſigns, or are under the influence of ſeditious perſons. Perhaps no mode is ſo efficacious as dividing them into ſmall parties, and diſarming them in detail.

When armies, or bodies of ſufficient force to entitle them to deference, are compelled to ſurrender, it is generally contended by them, that their arms, artillery, and baggage ſhould be allowed them. This admits of various modifications. In ſome inſtances, where prudence dictates to a conquering general not to make any difficulties, but to get rid of an enemy, at any rate, the foregoing terms have been allowed, and the vanquiſhed force has been allowed to march away with all the honours of war; that is, colours flying, drums beating, matches lighted, bayonets fixed, ſwords drawn, cannon untimbered, and, in fact, as though in a ſtate of defiance. In other inſtances, the honours of war are granted conditionally, and the proceſſion ceaſes after evacuating a fortreſs; when the garriſon march out, (but not away) in full diſplay, and at an appointed ſpot, ſurrender their artillery, and after grounding their arms, and taking off their pouches and belts, move from, and ſurrender them to the victors. But even here we have many varieties; it being ſometimes a condition that the officers ſhall retain their ſide arms; in others, that they ſhall retain them until embarked only, ſo as to ſave appearances for a while.

According to the modern mode of warfare, we ordinarily find but little ceremony uſed; for the moſt part the whole ſurrendering as priſoners of war, and all delivering up their arms without reſervation. It is, however, uſual, and no doubt proper, to grant ſome honourable diſtinctions to an enemy who has refrained from pillaging, and has carried on his operations with as little injury as poſſible towards the country in general. Formerly there were particular rules faſtidiouſly eſtabliſhed among the great commanders, not leſs formal than their court ceremonies; but ſince our enemies have laid aſide all feeling, generoſity, and humanity, it has become indiſpenſably neceſſary for our generals to diſarm their priſoners, and to be very circumſpect in granting any indulgence, or honourable type, to perſons who are inſenſible to the dignity and pride of the military profeſſion.

On the concluſion of a peace, it is uſual for both ſides to diſarm. We have divers laws for diſarming papiſts, and all recuſants. Under king George I. a law was made for diſarming the Highlanders; none of whom, except peers, or gentlemen of 400*l. per ann.* are to wear any arms in the field, on the road, or at market. 1 Geo. I. ſtat. 2. cap. 54.

The game law has, in effect, diſarmed all the common people of England, having under 100*l.* a year in landed eſtate, except the ſervants of lords of manors. Yet, by the ancient policy of England, the whole nation was obliged to bear arms. See Game *Laws*.

DISARRHENUM, in *Botany*, (from δις, *double*, and αρρην, a *male*, becauſe of the two lateral male florets,) a genus founded by La Billardiere, in his Novæ Hollandiæ Plantarum Specimen, of which he gives a plate and the following account. Claſs and order, *Polygamia Monoecia* (rather *Triandria Digynia*). Nat. Ord. *Gramina*.

Eſſ. Ch. *Cal.* Glume of two valves, containing three florets, the central one hermaphrodite, the two lateral ones male. The former has a *Corolla* of two valves, without awns; three ſtamens; two ſtyles; one ſeed: the latter have the outer valve of the corolla awned; and three ſtamens.

D. *antarcticum*. A graſs half a fathom and more in height, with a ſtriated *ſtem*, and ſquarroſe ſtriated *leaves*. *Stipula* torn. *Panicle* rather leaning to one ſide. The habit is that of a *Holcus*, and the author ſuſpects *H. latifolius* and *odoratus* of Linnæus may prove of this genus, and that *Ariſtida antarctica* of Forſter may be the very ſame plant.

DISBAND, in a *Military Senſe*, relates to the diſorganization of a body of men, by allowing the ſoldiers to retire from the ſervice; in contradiſtinction to *reducing* a battalion by draughting the men into other battalions. When a

corps

corps is disbanded, its colours are, in general, deposited in some public arsenal, and the drums, &c. are preserved in the state in which they are at the time of disbanding; especially if it be a regiment of the line; in order that the whole may be in readiness whenever the same number may be again brought upon the strength of effective regiments. In disbanded regiments the officers are put on half pay. In some services, when regiments have been disbanded, or rather *broke*, for bad behaviour, their colours have been burnt, and the numbers of those regiments kept vacant, no corps being allowed to supply the place of the disgraced regiments. But a regiment is not considered as disbanded until it has ceased in every case to be effective: then, when, in unfavourable climates a regiment may be so much reduced as to render it unfit for field service, it is usual to draught the privates, and to send the officers, serjeants, and corporals home with the colours, to recruit the corps to its former strength; in fact, to raise a new one. But if there should appear no further occasion for their services, the commissioned officers are placed on half pay, and the non-commissioned are removed to some other regiment. This is literally *disbanding*, and can only take place by order of his majesty; it not being within the authority of any other person to abrogate the king's commission; though generally, on foreign stations, discretionary power is vested in local commanders in chief to approve, and to carry into effect, the sentences of courts-martial, whereby those officers who trespass against the articles of war may be deprived of their commissions, or eventually suffer capital punishment.

The disbanding of a corps is attended with some form. The king's commission is usually read on the parade, by the governor, or deputy-governor, of the fortress, or by the commanding officer of the district, and the colours are marched away under a guard; the arms and the accoutrements, together with the stores, being all delivered up to persons appointed to receive them. The soldiers receive their written or printed discharges, and are, in some cases, forwarded to their respective homes at the public expence; the billets are cancelled, and the whole disperse. This scene cannot be witnessed without some emotion: men who have sustained their country's honour, and who are mutually indebted to each other's personal prowess, for succour in the hour of danger, associated too for probably many, many years, cannot but feel, intermingled with the joy of approaching their long estranged families, some reluctance at the separation from each other, and from officers who had gained their affections by kindness, and good example!

DISBOSCATION, Disboscatio, a turning wood-ground into arable or pasture, an assarting. See Assart.

DISBURDENING *of* Trees, in *Gardening*, the taking off leaves and fruits when too numerous, that those left may grow the larger.

DISC, or Disk, *Discus*, in *Antiquity*, a kind of round quoit, or a piece of stone, or metal, or wood, about a foot over, used by the ancients in their exercises.

The discus of the ancients was flat and round, resembling the apparent figure of the sun.

The exercise of the discus was one of those practised in the solemnities of their public games; it consisted in pitching, or throwing a discus either upward, or straight forward; and he who threw it highest, or farthest, bore away the prize.

Those who practised at this game were called *discoboli, i. e.* throwers of the discus.

The poets tell us, that Hyacinth, a favourite of Apollo, playing at the discus with that god, was killed by a blow of Apollo's discus, which his rival Zephyrus diverted from its course, and cast on the boy's head.

The discus was thrown by means of a little cord made of hair, as appears from Claudian, lib. ii. in Eutrop. carm. 20. ver. 359, et seq. Ovid describes this sport, Metam. lib. x. ver. 175. The Romans learnt the game of the discus of the Greeks, and practised it among themselves. Dempster, Paraleip. in Rosin. Antiq. Rom. lib. v. cap. 1. and Pet. Faber. Agonisticon, lib. ii. cap. 1. treat of the diversion of the discus.

Disc, or *Disk*, in *Astronomy*, the body or face of the sun, or moon; such as it appears to us. For, though they are really spherical bodies, they are apparently circular planes.

The disc is conceived to be divided into twelve equal parts, called digits; by means whereof it is that the magnitude of an eclipse is measured, or estimated. See Digit and Eclipse.

Disc, *illuminated, of the earth*. See Circle *of illumination*.

Disc, in *Optics*, the magnitude of a telescope glass; or the width of its aperture, whatever its figure be, whether a plain, convex, meniscus, or the like.

Disc, in the Greek *Liturgy*, is nearly the same thing with the patena in the Latin. See Patena.

In the Greek church, the consecrated bread is laid on a discus, as in the Latin church it is on a patena. The discus only differs from the patena, in that it is bigger and deeper, as resembling a plate, which was the proper signification of the word discus among the ancients.

DISCALCEATED, (Discalceati, unshod,) certain orders or reformations of friars and nuns, so called from their going bare-footed, or using sandals instead of shoes.

DISCANT, in *Music*, from *discantus*, Lat. sounding twice. The English verb, *to descant*, is derived from the Fr. *déchant*, which means the same thing. About the time that the organ was received in churches and convents, the Gregorian chant, or plain-song, began to be organized by voices, in the manner which was afterwards called discant, and the simultaneous correspondence of that harmonical series which constitutes concert, or music in different parts, has been variously expressed by writers on the subject, since it was first suggested. The most ancient names given to it by Hubald, Odo, and Guido, are diaphonia, and organum; and discantus, triplum, quadruplum, diatessaronare, quintoier, motetus, medius, and tenore, are all words that preceded the term counterpoint. As those implied singing upon a plain song, extempore; and contrapunctum, written harmony.

The most ancient authority which Du Cange gives for the use of the word discantus, discantare, is from Hugotio of Vercelli, bishop of Ferrara, and the first definer of decretals, who died 1212. This author says, "decantare est valde cantare, discantare et excantare, id est, discantare." It is called by Guido, in his Micrologus, organum, and organizare, according to Du Cange, is canere in modum organi; and among his authorities, he gives the following definition from the catholicon, or lexicon, of John de Janua, written in 1286; "Organizare organo cantare; jouer ou chanter en orgres, organisor, to play or sing like the organ."

The subject of the fifth chapter of Franco's tract in the Bodleian library, Oxon, in discant, and the agreement of different voices. Discant, in the infancy of what was afterwards called counterpoint, and, in old English, faburden, implied a double chant or melody.

There are several curious particulars concerning discant in the writings of the celebrated Gerson, chancellor of the church and university of Paris at the beginning of the 15th century.

century. According to him, the ground-work of all diſcant was the plain chant; and, in his treatiſe of the education of children for the choir of Notre Dame, he enjoins a particular attention to chanting, counterpoint, and diſcant, as the three moſt eſſential branches of their ſtudy.

Diſcant, by the Italians, is called contrappunto alla mente, or extemporaneous harmony. Padre Martini, "ſaggio di contrappunto," heard this kind of harmony, a quattro voci, in four parts, produced in great perfection in the church of St. John Lateran, in Rome, 1747. It is called by the French "Chant ſur le livre." To compoſe a part upon ſeeing only the chant upon which it is to be built is very difficult, and requires, ſays Rouſſeau, great knowledge, habit, and quickneſs of ear in thoſe who practiſe it; and the more ſo, as the key is not always ſo eaſily found as in modern muſic. However, there are muſicians in the church ſo well verſed in this kind of ſinging, that they lead off, and even carry on, fugues extempore, when the ſubject will allow it, without confounding or encroaching upon the other parts, or committing a ſingle fault in the harmony.

DISCEIT, in our *Old Writers*. See DECEIT and DECEPTIONE.

DISCERI, in *Ancient Geography*, a people inhabiting the interior of Africa, ſaid by Pliny to have been ſubdued by Cornelius Balbus.

DISCERNING, an act of the mind, whereby it diſtinguiſhes between ideas.

On this faculty of diſcerning depend the evidence and certainty of ſeveral, even general propoſitions, which paſs for innate truths; and which in reality flow from this clear diſcerning faculty of the mind, whereby it perceives two ideas to be the ſame, or to be different.

In being able nicely to diſtinguiſh one thing from another, where there is the leaſt difference, conſiſt in great meaſure that exactneſs of judgment, and clearneſs of reaſon, which are to be obſerved in one man above another; which are quite oppoſite to wit: this conſiſts moſt in the aſſemblage of ideas, and putting thoſe together with quickneſs and variety, which have the leaſt reſemblance to form agreeable viſions: whereas judgment ſeparates carefully thoſe ideas, wherein can be found the leaſt difference, to prevent error and deluſion. To the well diſtinguiſhing of our ideas it chiefly contributes, that they be clear and determinate; and when they are ſo, there will not ariſe any confuſion, or miſtake about them, though the ſenſes ſhould convey them from the ſame object differently on different occaſions. See JUDGMENT.

DISCEUS, or DISCIFORMIS *Cometa*. See DISCUS.

DISCHARGE, in *Electricity*. See CHARGE.

DISCHARGE, in *Law*, on writs and proceſs, &c. is, where a man is confined by ſome legal writ or authority, and doth that which by law he is required to do, he is releaſed or *diſcharged* from the matter for which he was confined. If one be arreſted by a *latitat* out of B. R., and the plaintiff do not file a declaration againſt the defendant in priſon in two terms, he ſhall be diſcharged on common bail. (1 Lil. Abr. 470.) Alſo where a defendant on arreſt is admitted to bail, if the bail bring in the principal before the return of the ſecond *ſcire facias*, iſſued out againſt them, they ſhall be diſcharged. If an obligee diſcharges one joint obligor when ſeveral are jointly bound, it diſcharges the others. (Merch. 129.) And a man may diſcharge a promiſe made to himſelf, &c. (Cro. Jac. 483.) See ACQUITTAL, CHARGE, HABEAS CORPUS, &c.

DISCHARGE, in *Military Language*, is the diſmiſſion of a ſoldier from the troop or company to which he belonged, either by his own requeſt, or when after long and faithful ſervice, he is entitled to his majeſty's bounty. See DISMISS.

DISCHARGE, *To*, in *Sea Language*, ſignifies to unload a ſhip, or take out her ſtores, ammunition, artillery, &c. When applied to the crew, it implies to diſband them from immediate ſervice.

DISCHARGE *of Fluids* through apertures, orifices, &c. The various important particulars which demand attentive conſideration relative to the diſcharge of fluids through apertures made in the ſides of veſſels in which thoſe fluids are contained; are the quantity of fluid diſcharged in a given time through a given aperture; the form, direction, impetus, and velocity of the ſtream; and the forms of apertures, pipes, &c. the moſt advantageous for anſwering particular purpoſes. The obvious extent and importance of the ſubject have induced the greateſt philoſophers and mathematicians of the laſt century or two, to exert themſelves in the inveſtigation of the above-mentioned particulars; and if our preſent knowledge of the ſubject has not as yet attained its ultimate degree of perfection; it muſt, however, be acknowledged, that the mathematical theory of hydraulics, aſſiſted by the known reſults of practical inveſtigations or experiments, is now capable of foretelling the reſult of any particular new conſtruction, in ſome caſes *exactly*, and in moſt others ſo very near the truth, as to differ from it by at moſt one-fifth of the whole. In this ſubject, the determinations of the theoretical propoſitions do not in general agree with the reſults of actual experiments; not on account of any defective demonſtration, but becauſe the demonſtrations cannot be eſtabliſhed upon all the concurring circumſtances; ſome of which are of a fluctuating nature, whilſt the extent of others is either not known or cannot be duly appreciated. Thoſe circumſtances are the peculiar qualities of fluids, which vary according to homogeneity, purity, temperature, &c; the attraction of aggregation, or corpuſcular attraction, which differs conſiderably in water, oil, mercury, &c; the friction againſt the ſides of the veſſels; the reſiſtance of the air; the ſize of the veſſel in proportion to the aperture through which the fluid iſſues; the ſhape of the aperture; the different directions in which the various parts, or (as they are otherwiſe called) the various *filaments*, of the fluid are obliged to run towards the aperture; and the vortices or irregular motions, that are communicated to the fluid by a variety of cauſes; even by an obſtacle preſented to the ſtream at ſome diſtance from the aperture. However, it muſt be acknowledged, that the conſtant attention which is paid to the reſults of experiments renders the theory daily more extended and more preciſe.

For the ſake of perſpicuity, we ſhall ſeparate the theoretical propoſitions from the experimental part; but conſidering the intricacy, and at the ſame time, the inſufficiency of the theory, we ſhall only ſtate the leading theoretical propoſitions; referring at the ſame time the inquiſitive reader to other works written expreſsly on the ſubject; and ſhall then add, in a more extenſive manner, an account of the moſt uſeful experimental inveſtigations, whence the reader may be enabled to adopt the moſt uſeful practical deductions, without his being perplexed by intricate, and in moſt caſes inſufficient calculations.

Propoſition I. When water, or other non-elaſtic fluid, runs through a pipe or tube of an uniform ſhape; equal quantities of it paſs through every parallel ſection of the tube; *viz.* the water runs with equal velocity through every one of thoſe ſections.

This is ſo very evident, conſidering that the ſame quantity of fluid muſt paſs through the ſame ſection in the ſame time, as to require no farther illuſtration; but it muſt be obſerved,

obſerved, that though the water runs with the ſame velocity through every ſection of the tube, yet it does not run with equal velocity through every part of the ſame ſection. Its motion is ſwifter towards the middle, and ſlower towards the ſides of the tube, where it is retarded by the friction againſt the ſides.

Propoſition II. When water, or other non-elaſtic fluid, runs through a pipe or tube, which is kept continually full by means of a proper ſupply; but which is not of an uniform ſhape; then the velocities of the fluid in different ſections will be inverſely as the areas of the ſections.

Since the tube is always full, the ſame quantity of water muſt paſs through every ſection of it in the ſame time; but if the area of one ſection be half as great as the area of another ſection, the ſame quantity of water cannot paſs through both ſections at the ſame time, unleſs it paſſes through the former ſection with double the velocity with which it paſſes through the latter. If the area of the former ſection be one-third or one-fifth, of the area of the latter, the ſame quantity of water muſt paſs through the former with a velocity which is three times or five times the velocity with which it paſſes through the latter. Hence, in general, the velocities muſt be inverſely as the areas of the ſections.

Propoſition III. If a fluid, as water, flowing through a very ſmall orifice in the bottom of a veſſel, be kept conſtantly at the ſame height in the veſſel, by being ſupplied as faſt above as it runs out below, the velocity of the effluent fluid will be equal to that, which a heavy body would acquire in falling freely through the height of the fluid above the orifice.

Let M N O P, *Plate* I. *Hydraulics*, *fig.* 6, repreſent a veſſel filled with a non-elaſtic fluid up to the level G H; M P the bottom in which is the aperture C D (very ſmall in compariſon with M P); C I K D the column of the fluid ſtanding directly above the aperture, and C A B D the loweſt plate of the fluid immediately contiguous to the aperture. Alſo let v denote the velocity which a heavy body would acquire in falling freely through B D, the height of the plate, and V the velocity acquired by the ſame plate during its deſcent through the ſame ſpace until it is diſcharged by the preſſure of the column C I K D. If we ſuppoſe the loweſt plate of fluid A C B D to fall as a heavy body through the height B D, its moving force will be its own weight. Again, ſuppoſe it to be accelerated by its own weight, together with the preſſure of the ambient fluid, about the column C I K D; *viz.* by the weight of the column C I K D, through the ſame ſpace; that is, while it is accelerated from quieſcence until it is actually diſcharged: then (agreeably to the eſtabliſhed laws of dynamics) the velocity in the former caſe will be to that in the latter, as the moving forces and the times in which they act directly, and the quantities of matter moved inverſely. See DYNAMICS. But the moving forces are to each other as the heights B D and K D; the times in which they act are inverſely as the velocities, the ſpace through which the body is accelerated, being given; and the quantities of matter moved are equal: therefore, $v : V :: \frac{BD}{v} : \frac{KD}{V}$; whence $v^2 : V^2 :: BD : KD$; or $v : V :: \sqrt{BD} : \sqrt{KD}$. Now v is the velocity which a heavy body would actually acquire in falling through the ſpace B D; conſequently V the velocity of the effluent fluid is that which a heavy body would acquire in falling through K D, the whole altitude of the fluid above the orifice.

Corollaries.

1. In the ſame manner it may be ſhewn, that if a pipe be inſerted horizontally in the veſſel M N O P, *fig.* 7, the plate of fluid A C B D will be diſcharged with the ſame velocity as before (if its centre of preſſure be of the ſame depth), whatever be the thickneſs of the plate; this velocity not depending upon a continual acceleration through the length of the tube, otherwiſe the effluent fluid could not attain its full velocity, until a column had been diſcharged whoſe baſe is equal to the orifice, and height equal to the length of the tube: whereas we find by experience, that this full velocity can be attained by the thinneſt plate which can be let eſcape from the aperture.

2. The velocities and quantities diſcharged at different depths, are as the ſquare roots of the depths.

3. The quantity run out in any time is equal to a cylinder, or priſm, whoſe baſe is the area of the orifice, and its altitude the ſpace deſcribed in that time by the velocity acquired by falling through the height of the fluid.

So that if h denote the height of the fluid,

a, the area of the aperture,

g, $32\frac{1}{6}$ feet, or 386 inches, and

t, the time of efflux; we ſhall have for the quantity diſcharged, $Q = at\sqrt{2gh}$;

Or, when a and h are expreſſed in feet, $Q = 8.0208\, at\sqrt{h}$, feet.

When a and h are expreſſed in inches, $Q = 27.7387\, at\sqrt{h}$, inch.

If the orifice is a circle whoſe diameter is d, then $0.785398\, d^2$ muſt be ſubſtituted for a;

And when d and h are expreſſed in feet, $Q = 6.29952\, d\sqrt{h}$, feet.

When d and h are expreſſed in inches, $Q = 21.78592\, dt^2\sqrt{h}$, inches.

And from either of theſe it will be eaſy to find either a, t, or h, when the other three quantities are given.

4. The force with which the effluent water impinges againſt any quieſcent body, is proportional to the altitude of the fluid above the orifice. For the force is as the velocity multiplied by the quantity of matter; but the quantity diſcharged in a given time is as the velocity; therefore the force is as the ſquare of the velocity; that is, by the demonſtration of the propoſition, as the height of the fluid.

5. The water ſpouts out with the ſame velocity whether it be downwards, or upwards, or ſideways; becauſe the preſſure of fluids is the ſame in all directions at the ſame depth.

6. Hence, if the *adjutage* (*viz.* the laſt appendage or termination affixed to the aperture) be turned upwards, the jet will aſcend to the height of the ſurface of the water in the veſſel. In practice, however, the jet is found to be ſhorter than the height of the fluid in the reſervoir; which is owing to the friction of the fluid againſt the ſides of the aperture, and againſt the ſurrounding air. The difference between the height of the jet and that of the fluid in the veſſel or reſervoir, will be ſhewn under the article JET.

It is now neceſſary to obſerve the ſame thing that has been already obſerved in propoſition I. *viz.* that the velocities of the effluent water, as mentioned in this propoſition and its corollaries, muſt be underſtood of thoſe filaments only of the fluid which paſs through the centre of the aperture, which are ſuppoſed to ſuffer no retardation; for thoſe filaments which paſs by the ſides of the aperture are conſiderably retarded by the friction againſt thoſe ſides, and other circumſtances, in conſequence of which they produce a remarkable configuration of the ſtream, which will be deſcribed hereafter.

Propoſition IV. When a veſſel is left to diſcharge itſelf gradually through an orifice in its bottom, if the area of the ſection

ſection parallel to the bottom be every where the ſame, the velocity of the ſurface of the fluid, and, conſequently, the velocity of the efflux, will be uniformly retarded.

For (by Prop. II.) the velocity of the deſcending ſurface is to the velocity at the ſurface, as the area of the orifice to the area of the ſurface, which is a conſtant ratio; conſequently, the velocity of the deſcending ſurface varies as the velocity at the orifice, or as the ſquare root of h; that is, the velocity of the deſcending ſurface varies as the ſquare root of the ſpace which it has to deſcribe: ſo that this exactly correſponds with the caſe of a body projected perpendicularly upwards, where the velocity is as the ſquare root of the ſpace to be deſcribed: whence, as the retarding force is conſtant in the inſtance referred to, it muſt alſo be conſtant in the caſe before us, and the retardation uniform. From this compariſon we deduce the following obvious corollaries.

1. The quantities of water in a priſmatic veſſel diſcharged through an aperture in the bottom, decreaſe in equal times as the ſeries of odd numbers 1, 3, 5, 7, 9, &c. taken in an inverted order.

2. The quantity of water contained in an upright priſmatic veſſel is half that which would be diſcharged in the time of the entire gradual evacuation of the veſſel, if the water be kept always at the ſame altitude.

Whoever wiſhes to examine the theoretical part of the preſent ſubject more at large, may conſult the following works. S'Graveſande, Nat. Phil. Jo. Bernouilli on the motion of water in pipes, C. Peter. IX. X. Euler on the motion of water in pipes, A. Ber. 1752. Alſo his Principles of Hydraulics, ibid. 1755. On the re-action of water in pipes, N. C. Peter. VI. Gregory's Mechanics. b. 4. c. 1.

We muſt now proceed to treat of the experimental part of the preſent ſubject; and with reſpect to this we ſhall only advert to the more important experiments and the moſt uſeful reſults.

The ſtream of water which iſſues out of a hole tends to carry away in its direction any other fluid, or any other body ſufficiently light, which may happen to be near it. This is what profeſſor Venturi calls *the lateral communication of motion in fluids*. But by this lateral communication of motion to contiguous bodies, the celerity of the fluid itſelf is checked more or leſs, and its courſe is partly diverted from that direction which it would otherwiſe follow. Thus, in *fig.* 8, which repreſents the upper ſurface of two veſſels contiguous to each other, and full of water, as high as the hole or aperture A. If by pouring more water into the veſſel B, a ſtream of water be cauſed to flow through A, into the veſſel C, this ſtream will carry away the water from the parts *e e*, towards C. But the depreſſion, or deficiency, of water at *e e*, is replaced by the water from the adjacent parts *d d*, which are repleniſhed from the next, and ſo on. This produces eddies at *e d*, *e d*. This phenomenon may be rendered more apparent by throwing a little milk into the veſſel B, or by letting ſmall light bodies float upon the ſurface of the water.

When a ſtream comes out of a hole, as at A, *fig.* 9, if a thread, a feather, or other light body be placed very near it, the tendency of the ſtream to carry it towards B may be clearly perceived. This tendency is ſtill more evidently ſhewn by the following experiments.

Let a veſſel, open at top, be made of the form of the lateral repreſentation A D B, *fig.* 10, having one ſlant ſide. Let a cylindrical pipe, of about half an inch in diameter, and upwards of a foot in length, proceeding from a veſſel C, come ſtraight down into the veſſel A D B, and there let its termination F S be bent in the direction of the ſlant ſide B D. This done, fill the veſſel A D B with water, then pour water into the veſſel C, ſo that the water running down the pipe E F S, may form the jet S K. It will be found that the water of the veſſel A D B is carried away by the ſtream S K, and this veſſel is thereby almoſt entirely emptied.

To an aperture on the ſide of the veſſel A B, *fig.* 11, a pipe 1.6 inch in diameter, and little more than five inches in length, was adapted in an horizontal direction by profeſſor Venturi. At E, diſtant 0.71 inch from the ſide of the veſſel, a bent glaſs tube, E F G, was joined, whoſe cavity was opened into that of the pipe, whilſt its other extremity was immerſed in coloured water, which was contained in a ſmall veſſel G.

When, by pouring water into the veſſel A B, a ſtream was made to flow out at D, the coloured water was ſeen to riſe conſiderably in the lower leg of the glaſs tube. The experiment being repeated when the deſcending leg F G of the glaſs tube was only 6.4 inches longer than the part E F; the coloured water of the veſſel G roſe through the glaſs tube, and mixing with the other water, flowed with it out of the pipe at D; and in a ſhort time the veſſel G was emptied.

This lateral communication of motion takes place whether the diſcharging pipe is directed horizontally, or upwards or downwards, or, in ſhort, in every direction, but it is more powerful when the ſtream is directed downwards, which is owing to the tendency that a deſcending ſtream has of dividing itſelf in conſequence of the acceleration of falling bodies; for that part of the ſtream which is juſt out of the aperture moves with leſs velocity than that which is farther off. When water runs out of an aperture in the thin ſide or bottom of a veſſel, as at A *fig.* 9. the ſize of the aperture being very ſmall in proportion to the ſide or bottom of the veſſel; the ſtream A B is not throughout of the ſhape of the aperture, nor is it of an uniform ſize. When the aperture is circular, the diſtance of the narroweſt part of the ſtream, from the inſide ſurface of the veſſel, is about equal to the diameter of the aperture. This narroweſt part of the ſtream has been called the contracted vein (*vena contracta* by Newton, who firſt took particular notice of it) from which place forwards the ſtream grows larger, and ſometimes divides itſelf into different parcels.

The diameter of the contracted vein, or of the narroweſt part of the ſtream, has been differently eſtimated by different obſervers: and probably the difference has been occaſioned by ſome unadverted variation in the ſize of the veſſel, thickneſs of the ſide in which the aperture was made, &c.—Newton found that at the diſtance of about a diameter of the orifice the ſection of the contracted vein was nearly in the ſubduplicate ratio of 2 to 1. Polenus makes the ratio of the diameters of the contraction and of the aperture to be as 11 to 13; Bernouilli, as 5 to 7; Du Buat, as 6 to 9; Boſſut, as 41 to 50; Eytelwein, as 16 to 25; Michelotti, as 4 to 5. Venturi nearly as 4 to 5. Venturi alſo obſerves that the contraction of the ſtream takes place at a greater diſtance

under

under ſtrong charges than in thoſe which have but little elevation. Michelotti alſo found that the ſtream was a little more contracted as the velocity was greater.

This contraction of the ſtream is undoubtedly owing to the various directions in which the fluid comes along the ſides and from every part of the veſſel, towards the aperture; and, in fact, when the aperture is very large in proportion to the ſize of the veſſel, the contraction of the ſtream is leſs apparent. Alſo, if the aperture be not in a plate ſufficiently thin, the vena contracta will not be perceived; for ſince the diſtance of that contraction from the inner ſurface of the veſſel is about equal to the diameter of the aperture, if the thickneſs, or rather the length of the aperture, exceed its diameter, as when a pipe is added to the aperture: then the contraction, or the tendency to form the contraction, takes place within the length of the aperture or pipe.

The various filaments of the fluid, which run from every part of the veſſel in oblique directions towards the aperture, partly croſs each other at the *vena contracta*; and this croſſing, or tendency to croſs, is one of the cauſes which enlarge the ſtream beyond that place.

The velocity of the water is not the ſame in every part of the ſtream; for ſince the ſame quantity of water muſt paſs through every tranſverſe ſection of it in a given time, the velocity (by prop. II.) muſt be inverſely as the area of each ſection. Therefore at the *vena contracta* the velocity is greater than at the aperture; and, indeed, in the different caſes this reduced area of the *vena contracta* ſhould be conſidered as the real area of the orifice through which the fluid iſſues, and its vertical diſtance from the upper ſurface of the fluid in the reſervoir as the height due to the velocity of the fluid iſſuing through this contraction, which, as has been already obſerved, is ſuch as a body would acquire by falling perpendicularly from the height of the fluid in the veſſel; whereas the velocity at the aperture itſelf is ſuch as a body would acquire by falling perpendicularly from the *half* of that height.

With reſpect to the quantity of fluid diſcharged, Mr. Boſſut's experiments, which were made with peculiar accuracy, demand particular notice. They are expreſſed in the following table, which exhibits the quantity of fluid diſcharged through orifices pierced in thin plates; in meaſures of the Paris foot royal, which is to the Engliſh foot, as 1066 to 1000. Boſſut's Hydrodyn. t. ii. p. 47.

Conſtant altitude of the Water in the Reſervoir above the Aperture, in Paris Feet.	Theoretical Diſcharges in one Minute, through a circular Aperture of Tin, Diameters expreſſed in cubic Inches.	Real Diſcharges in the ſame Time, through the ſame Orifice, expreſſed alſo in cubic Inches.

The following is another ſet of experiments made by the ſame author with different apertures, in which the water was kept conſtantly at the altitude of eleven feet, eight inches, ten lines, from the centre of each aperture.

Experiments.		Cubic Inches furniſhed in one Minute.
1.	With an horizontal circular aperture, 6 lines in diameter	2311.
2.	With a circular horizontal aperture, 1 inch in diameter	9281.
3.	With a circular horizontal aperture, 2 inches in diameter	37203.
4.	With a rectangular horizontal aperture, 1 inch by 3 lines	2933.
5.	With a ſquare horizontal aperture, the ſide 1 inch	11817.
6.	With a ſquare horizontal aperture, the ſide 2 inches	47361.
	Conſtant height of water 9 feet.	
7.	Lateral circular aperture, 6 lines in diameter	2018.
8.	Lateral circular aperture, 1 inch in diameter	8135.
	Conſtant height of water 4 feet.	
9.	Lateral circular aperture, 6 lines in diameter	1353.
10.	Lateral circular aperture, 1 inch in diameter	5436.
	Conſtant height of water, 7 lines.	
11.	Lateral and circular orifice, 1 inch in diameter	628.

From theſe experiments we may derive the following deductions, *viz.*

1. The quantities of fluid diſcharged in equal times from different ſized apertures, the altitude of the fluids being the ſame, are to each other nearly as the areas of the apertures.

2. The quantities of water diſcharged, in equal times, by the ſame aperture, with different altitudes of water in the reſervoir, are nearly as the ſquare roots of the correſponding altitudes of the water in the reſervoir above the centre of the aperture.

3. That, in general, the quantities of water diſcharged, in the ſame time, by different apertures, and under unequal altitudes of the water in the reſervoir, are to each other in a compound ratio of the areas of the apertures, and the ſquare roots of the altitudes.

4. That, on account of the friction, the ſmalleſt apertures diſcharge leſs water than thoſe that are larger and of a ſimilar figure, the water in the reſpective reſervoirs being at the ſame height.

5. That of ſeveral apertures whoſe areas are equal, that which has the ſmalleſt circumference will diſcharge more water than the others, the water in the reſervoirs being at the ſame altitude, and this becauſe there is leſs friction. Hence circular apertures are moſt advantageous, as they have leſs rubbing ſurface under the ſame area.

Thus far we have treated of ſimple apertures; but if to the circular aperture on the ſide of a veſſel, there be applied a cylindrical pipe of the ſame diameter, and whoſe length is equal to from two to four times that diameter, as A B, *fig.* 12, then a greater quantity of water will be diſcharged through it, than through the ſimple aperture in an equal portion of time, every other circumſtance remaining the ſame; the quantities of fluid diſcharged in theſe two caſes being as 133 to 100 nearly.

The pipe A B, or any other prolongation of any ſhape which is adapted to the aperture of a veſſel, has been called the *adjutage*, from its property of promoting the diſcharge of the fluid.

It has likewiſe been obſerved, that the diſcharge, in a given time, is the ſame, whether the aperture be furniſhed with the abovementioned cylindric pipe, or with the pipe repreſented

repreſented in *fig.* 13, which differs from the former only by its having, cloſe to the ſide of the veſſel, a contraction nearly of the ſhape of the contracted vein.

If the laſt mentioned pipe be cut off at the contraction, and the firſt conical part only be left affixed to the aperture, as in *fig.* 14, then the diſcharge of water is rather leſs than from a ſimple aperture; but it is probable, that it would be quite the ſame, were it poſſible to make the conical adjutage exactly of the ſhape of the natural contracted vein; excepting, however, the effect of friction.

If to this conical part a cylindrical tube of the diameter of the ſmall part of the conical pipe, be applied, as in *fig.* 15, the diſcharge of fluid will thereby be diminiſhed, and more ſo according as the length of the cylindrical part is increaſed.

If to the ſmall conical part of the adjutage, *fig.* 14, a diverging pipe, *viz.* another conical tube be applied, as in *fig.* 16, the diſcharge of water will thereby be increaſed within a certain limit; for it appears that when the divergency is greater than 16 degrees, the effect ceaſes entirely, and that the greateſt diſcharge takes place, when the divergency is equal to an angle of about three degrees. And if between thoſe two conical parts a cylindrical tube be interpoſed, as in *fig.* 17, then the diſcharge is again diminiſhed, but not nearly ſo much as if the outer conical part were removed. It appears from the obſervations of Venturi, that with any length of intermediate pipe, the diſcharge is always promoted by the abovementioned conical termination, which would be of infinite practical uſe; for the diſcharge might be promoted without the enlargement of the pipe; and in moſt caſes ſo it actually proves to be; but Mr. Eytelwein obſerves, that if the pipe, or tube, be very long, the advantage produced by the abovementioned conical termination, becomes inſenſible or nearly ſo. Profeſſor Venturi, in order to determine the preciſe quantity of the effect, which each of the abovementioned conformations of diſcharging pipes produced, inſtituted an accurate ſet of experiments, which we ſhall conciſely ſubjoin as being of conſiderable importance in practical hydraulics.

The ſame quantity of water, (*viz.* 4845 Engliſh cubic feet) flowed out of the ſame veſſel or reſervoir, which was kept conſtantly full, through the following adjutages, in the annexed times, which are expreſſed in ſeconds. The altitude of the water in the veſſels, above the level of the centre of the outer aperture of the adjutage, was always equal to 34,642 Engliſh inches.

Through a ſimple circular aperture in a thin plate, the diameter of the aperture being equal to 1.6 inches, in - - - - - 41″

Through a cylindrical tube of the ſame diameter as above, and 4.8 inches long, as in *fig.* 12, in - - 31″

Through the tube, *fig.* 13, which differs from the preceding, by having the contraction in the ſhape of the natural contracted vein, in - - - - 31″

Through the ſhort conical adjutage, *fig.* 14, which is only the firſt conical part of the preceding, in - 42″

Through the pipe, *fig.* 15, which conſiſts of a cylindrical tube, adapted to the ſmall conical end of *fig.* 14, and of the ſame diameter; A D being 3.2 inches long, in - - - - - 42″.5

Through the like adjutage, but longer, A D being 12.8 inches long, in - - - - - 45″

Through the like, ſtill longer, A D being 25.6 inches, in - - - - - - - - 48″

Through an adjutage conſiſting of the ſimple tube of *fig.* 12, placed over the conical part of *fig.* 14, in - 32.″5

Through the double cone, *fig.* 16, the dimenſions of which are, A B = E F = 1.6 inches, A C = 0.977 inches, C D = 1.376 inches, and the length of the outer cone = 4.351 inches, in - - 27″.5

Through the adjutage, *fig.* 17, conſiſting of a cylindrical tube 3.2 inches long, and 1.376 inches in diameter, interpoſed between the two conical parts of the preceding, in - - - - - 28″.5

The effect of the above-mentioned adjutages is the ſame, whether they be adapted to the ſide, or to the bottom of the veſſel, or in any other direction, (ſince fluids preſs equally in every direction at the ſame depth) provided every other circumſtance be the ſame; ſuch as the capacity and form of the reſervoir, the altitude of the water above the level of the centre of the outer aperture of the adjutage, &c.

All flexures, and all ſorts of internal contractions, enlargements, elongations, ſinuoſities, and projections, in the conducting pipe, diminiſh more or leſs the quantity of diſcharge. The cauſe of this retardation, or diminution of the diſcharge, is undoubtedly owing to the eddies, and to the croſſings of the various filaments of the fluid, which, according to what has been obſerved above, muſt neceſſarily take place at thoſe irregularities. This may be rendered ſufficiently evident, if an irregular glaſs pipe be applied to a pretty large veſſel full of water, in which ſome light bodies, as ſome powdered amber, be mixed; for amber being nearly of the ſame ſpecific gravity as water, by the motion of its particles it will clearly ſhew the various and irregular directions of the water within the tube.

All eddies and croſs directions muſt unavoidably tend to deſtroy part of the moving force. The diſcharges out of a ſtraight tube, a curved tube in a quadrantal arc, and an elbowed tube forming a right angle (when they are all ſituated horizontally and in ſimilar circumſtances) are nearly as 70, 50, and 45; whence it appears, that ſharp angular bendings hinder the paſſage of the fluid conſiderably more than thoſe of a regular curvature. The internal roughneſs of a pipe contributes likewiſe to diminiſh the diſcharge. Whenever an irregularity in the ſhape of the aperture, or ſome particular conformation of the veſſel, compels the particles of the fluid to run obliquely towards the aperture, a circular motion is thereby ſoon communicated to the fluid, and an hollow whirl is formed in the veſſel above the aperture. In conſequence of that circular motion, the particles of the fluid acquire a centrifugal force, which compels them to recede from the centre, or from the axis of motion, where of courſe a hollow is formed, which is larger or ſmaller, according as the rotatory motion of the fluid is more or leſs rapid. When this whirling motion is pretty conſiderable, if any light bodies, floating upon the water, happen to come within the whirl, they will be readily drawn downwards towards the aperture; for, ſince the ſpecific gravity of the fluid is greater than that of the bodies, the fluid will acquire a greater degree of centrifugal force, and will recede farther than thoſe bodies from the axis of the whirl.

We might now proceed to deſcribe the form and altitude of the ſtream of fluid, when its direction is either oblique, or perpendicularly upwards or downwards; but theſe particulars more properly belong to the articles JET and STREAM, which ſee. It is alſo neceſſary to obſerve, that in the courſe of the above-deſcribed experiments, remarks, &c. we have taken no notice of any other fluid beſides water; the reaſon of which is, firſt, that as water is the moſt general fluid, with whoſe action human affairs are naturally and artificially concerned, moſt of the experiments and inveſtigations have been made relatively to that fluid; and, ſecondly, when any uſeful reſults have been either theoretically or practically eſtabliſhed with reſpect to water, the application of the ſame

reſults to other non-elaſtic fluids may be eaſily made, by allowing for the peculiar ſpecific gravities, adheſive qualities, and other peculiar properties of thoſe other fluids.

Having thus far treated of the diſcharges of non-elaſtic fluids through apertures, &c. a ſimilar inveſtigation ought to follow with reſpect to the diſcharge, or tranſition, of aerial (*viz.* elaſtic) fluids through apertures, &c. Of this, however, we ſhall only ſubjoin a few of the more general particulars, without any theoretical demonſtration, or practical illuſtration; for, as thoſe tranſitions or diſcharges of elaſtic fluid, are entirely dependent upon that property by which they are diſtinguiſhed from water and other non-elaſtic fluids, they are much better explained, and much more eaſily underſtood, in conjunction with the explanation of that characteriſtic property, for which ſee the article PNEUMATICS, wherein the demonſtrations, together with practical remarks, reſpecting the following and other particulars, will be found. Air ruſhes from the atmoſphere into a vacuum, or into a veſſel exhauſted of air, with the velocity which a heavy body would acquire by falling from the top of an homogeneous atmoſphere; which height may be reckoned equal to 27818 feet.

Put D for the natural denſity of the air in the atmoſphere; δ the denſity of the air contained in a veſſel partly exhauſted; V for the velocity of air of the denſity D ruſhing into a void, and v for the velocity with which it will ruſh into the rarefied air of the denſity δ; then $v = V \times \sqrt{1 - \frac{\delta}{D}}$ is an expreſſion for the velocity with which the air of the atmoſphere will ruſh into a ſpace containing rarer air.

The diſcharge of elaſtic fluids through different apertures, or their paſſage through pipes of various ſhapes, lengths, curvatures, &c. is likewiſe variouſly affected by theſe circumſtances. It alſo differs according to the peculiar nature of the elaſtic fluid employed.

DISCHARGE *of charged electrics*. See the articles ELECTRICITY and LEYDEN PHIAL.

DISCHARGED WORK, in *Calico-Printing*. See PASTE-WORK.

DISCHARGER, in *Electricity*, is an inſtrument which, being interpoſed between the two coatings, or the two charged ſurfaces of a Leyden phial, electric jar, battery, &c. will enable the operator to diſcharge that jar, or battery, &c. without any danger to himſelf. For this purpoſe various inſtruments have been contrived; but the moſt eſſentially uſeful are of three ſpecies, the ſimpleſt of which has received the denomination of *ſimple diſcharger*, or *diſcharging rod*; the next has been called the *diſcharging electrometer*; and the third has been called the *univerſal diſcharger*, from its being capable of anſwering all the principal objects which may be deſired in diſcharging charged electrics. We ſhall now deſcribe thoſe inſtruments in the order of their ſimplicity.

The *Simple Diſcharger*, or *Diſcharging Rod*, is a metallic wire, about the ſize of a quill, ſometimes ſtraight, but more commonly bent, as in *Plate* III. *Electricity*, *fig.* 10, and generally having a metallic ball or knobbed termination at each end C, B. When a charged jar or battery is to be diſcharged, the operator holding the diſcharging rod by its middle A, firſt applies one end of it to the outſide coating of the jar, and then brings the other extremity of the rod in contact with the inſide coating, or with the wire, or knobbed wire, which communicates with the inſide coating of the jar, by which means the electric power will be conveyed from one ſide of the charged electric to the other, and thus the diſcharge is effected. With ſuch a diſcharging-rod, however, and when the jar or battery is very powerful, the operator is not quite ſafe; for, in the firſt place, he will feel ſome effect of the ſhock, in conſequence of what is called, in electricity, the *lateral ſhock*; and ſecondly, if he happens to touch, with any part of his body, any metallic communication to one ſide of the jar, he may run the riſque of having the whole ſhock through his body. In conſequence of this inconvenience, an inſulating handle has been added to the preceding diſcharging rod, as is ſhewn in *fig.* 11, where A B is a glaſs handle, having a braſs ferrule, B C, cemented upon its extremity, and the rod paſſes through a hole in the braſs ferrule at C. In uſing this diſcharging rod, the operator holds it by applying his hand at A, in which caſe he becomes perfectly ſeparated from the circuit of the diſcharge.

The principal defect of the preceding diſcharging rods is, that they cannot be conveniently adapted to electrics of various ſizes and various ſhapes; but this defect is entirely removed by the conſtruction repreſented in *fig.* 12, which conſiſts of a glaſs handle A, and two curved wires B, B, which are moveable, like a pair of compaſſes, by the joint C, which is fixed to the braſs cap of the handle A. The wires B, B, are pointed, and their pointed terminations enter the balls D, D, to which they are ſcrewed, and from which they may be unſcrewed at pleaſure. The advantages of this conſtruction are, that the operator has the opportunity of uſing either the knobbed, or the pointed terminations, according as the experiments may require. And as the wires are moveable, ſo that the extremities D, D, may be placed nearer to, or farther from, each other, the diſcharging rod may be adapted to ſmall as well as to large jars, or to a coated plate of glaſs, or, in ſhort, to all ſorts of charged electrics. Mr. Nairne contrived a diſcharger, which he uſed to put up in the boxes with his patent electrical machines, and to which he gave the name of the *luminous inſulated diſcharging rod*. It conſiſts of an arched glaſs tube A B, *fig.* 13. to the extremities of which two braſs balls are cemented, and the communication from one braſs ball to the other is formed by an iron chain which paſſes through the tube and almoſt fills the whole cavity of it. The glaſs tube paſſes through a hole in the wooden termination C of the handle. It is evident that ſuch a diſcharging rod cannot be adapted to jars of different ſizes. In making the diſcharge of a jar with it in a dark room, and even in the day light, luminous ſparks are ſeen between the links of the chain within the tube, in conſequence of which this diſcharging rod has obtained the epithet of *luminous*.

The *Diſcharging Electrometer* was originally contrived by Mr. Lane (ſee the Phil. Tranſ. for 1767), and its uſe is to enable an electrified conductor, or a charged electric, to diſcharge itſelf, when the intenſity of the electricity in it, or the height of the charge, has reached a certain particular degree, which degree the operator may vary at pleaſure. Since Mr. Lane's original invention, this inſtrument has undergone various alterations in the hands of different electricians; but the principle remains the ſame. *Fig.* 14, repreſents this inſtrument, A B C is all of braſs, *viz.* a braſs wire having two braſs balls A and B. To a hole in the braſs ball B the extremity of the bent glaſs arm, (which is a ſolid ſtick of glaſs,) is firmly cemented. To the extremity of the vertical part of this arm, a braſs ball F, having a proper ferrule, is cemented. E G is a braſs ſcrew that has a braſs ball at E, and a milled head at G. The female of this ſcrew is in the ball F, ſo that by turning the milled head G, the wire G E may be ſcrewed in or out, and, of courſe, the ball E may be ſituated within any required diſtance of the ball A. A divided ſcale D H is faſtened to the ferrule of the braſs ball F, and it contains the diviſions of inches and

tenths of inches, ſo diſpoſed, as to indicate the preciſe diſtance between the ſurfaces of the balls A and E, when the edge of the milled head is againſt any of thoſe diviſions.

Now ſuppoſe, that the wire C is fixed into a Leyden phial, or is connected with the inſide coatings of a battery, that the balls A and E are ſet at the diſtance of one inch from each other, and that a metallic wire, or chain, or other conducting communication, is formed between the outſide of the phial or battery, and the part F G of the diſcharging electrometer. Then let the electrical machine which charges the jar or battery be put in action, and it is evident, that when the charge is become ſo high as to be able to leap through the interval of one inch, *viz.* from the ball A to the ball E, the diſcharge will be made without the application of any diſcharging rod or any farther interference of the operator. Thus by leaving the apparatus undiſturbed, and continuing the motion of the electrical machine, ſhocks preciſely of the ſame ſtrength may be ſent through a human being or through any other ſubſtance, that may be interpoſed between the outſide coating of the jar or battery, and the part F G of the diſcharging electrometer.

If the wire C is fixed in a hole on the prime conductor of an electrical machine, and a communication be made between the part F G and the ground; then, on working the electrical machine, ſparks of the ſame ſtrength may be repeatedly obtained from the prime conductor. This equality of ſhocks or ſparks is of great uſe in a variety of experiments; but is particularly ſo in medical electricity.

In ſhort with the above Mr. Lane's electrometer, the magnitude of the diſcharge is indicated by the quantity of air through which it is forced to paſs between the two balls A, E, the diſtance of which may be varied at pleaſure. The power of an electrical machine may be eſtimated by the frequency of the ſparks which paſs at any given diſtance. Mr. Lane found that the quantity of electricity required for a diſcharge is ſimply as the diſtance of the ſurfaces of the balls A, E; the ſhocks being twice as frequent when this diſtance is only $\frac{1}{24}$th of an inch as when it is $\frac{1}{12}$th.

Mr. Nairne ſimplified this electrometer in the manner exhibited in *fig.* 15, which conſiſts of a crooked glaſs arm, having a wooden termination at each end: the termination at A is conical, and fits a hole in the prime conductor of the electrical machine. The dotted circle in the figure repreſents the conductor end-ways. Through the other wooden termination, B, of the electrometer, a wire paſſes, which has a braſs ball at each end: this wire may be moved backwards and forwards in a hole through the wooden end B, and thus the inner braſs ball may be ſet at any required diſtance from the prime conductor. The farther management of this electrometer is the ſame as the preceding.

Another ſort of diſcharging electrometer is repreſented in *fig.* 16, where B C is a wire knobbed at each extremity, and moveable, like the beam of a balance, upon the pillar P. A is another braſs ball fixed upon another pillar, and a third pillar, which is capable of adjuſtment, up or down, is at Q, and upon this pillar, which holds a little ſtage, the ſubſtance through which a ſhock is required to be paſſed, muſt be ſituated between the extremities of two wires, one of which has a knob D. Now, when the communication is made between the inſide coating of the Leyden phial and the ball A, alſo between the outſide of the phial and the wire S; then, on charging the jar, at a certain period of the charge, the repulſion which takes place between the balls A and B, will elevate B, and, of courſe, depreſs C, ſo as to bring this near D, and effect the diſcharge.

Other ſorts of diſcharging electrometers may alſo be ſeen in the Philoſophical Magazine, vol. xi. Cuthbertſon's Electricity, &c,

The *Univerſal Diſcharger* was invented by Mr. Henly, and is repreſented in *fig.* 17. It conſiſts of the following parts. A is a flat board, fifteen inches long, four inches broad, and one thick, or nearly of theſe dimenſions. This board forms the baſe of the inſtrument. B, B, are two glaſs pillars, cemented in two holes upon the board A; and furniſhed at their tops with braſs caps, each of which has a turning joint, and ſupports a ſpring tube, through which the wire D C ſlides: each of theſe caps is compoſed of three pieces of braſs, connected ſo, that the wire D C, beſides its ſliding through the ſocket, has two other motions; *viz.* an horizontal and a vertical one. Each of the wires D C, D C, is furniſhed with an open ring at one end, and at the other end has a braſs ball D, which, by a ſhort ſpring ſocket, is ſlipt upon its pointed extremity, and may be removed from it at pleaſure. E is a ſtrong circular piece of wood, five inches in diameter, having, on its ſurface, a ſlip of ivory inlaid, and furniſhed with a ſtrong cylindrical foot, which fits the cavity of the ſocket F, which is faſtened into the middle of the bottom board, and has a ſcrew G, which ſerves to faſten the foot of the circular board E at any required height. H is a ſmall preſs belonging to this inſtrument; it conſiſts of two oblong pieces of board, which may be preſſed againſt each other by means of two ſcrews *a*, *a*: the lower of theſe boards has a cylindrical foot equal to the foot of the circular board E. When this preſs is to be uſed (and its uſe is to hold any thing through which a ſhock is to be paſſed), it is fixed into the ſocket F, inſtead of the circular board E, which muſt, in that caſe, be removed.

From what has been ſaid above, reſpecting the other diſchargers, it will be eaſily underſtood, that this univerſal diſcharger may be adapted to anſwer every purpoſe, by connecting the ends C, C, of the wires with the ſides of the Leyden phial, and putting the ſubſtance through which the ſhock is to be paſſed between the braſs balls D, D, upon the board E, or between the boards of the preſs H. The balls D, D, may be unſcrewed, and the pointed extremities of the wires may be uncovered, which is of uſe in certain experiments.

DISCHARGING OF COLOUR, is frequently employed by dyers, to produce particular patterns upon the dyed ſtuffs. A manufacture of this kind has lately been introduced and proſecuted to great extent in the weſt of Scotland, for the purpoſe of manufacturing Bandana handkerchiefs, in imitation of thoſe imported from India. The material of which the fabric conſiſts is cotton, and the cloth is ſometimes tweeled, and ſometimes woven plain. The ground of the handkerchief is generally of the faſt dye, commonly known by the appellation of Turkey red, and this colour being afterwards diſcharged in particular places, a number of white ſpots are interſperſed upon the red ground. The proceſs is by no means complex, but as the manufacture is recent, has hitherto been chiefly, if not entirely, confined to the diſtrict where it originated, and has been much admired; an account of the engine employed, and of the proceſs, may perhaps deſerve ſome attention. In the Indian Bandanas, the white ſpots are generally placed in cluſters in the diagonal or diamond direction, and this diſtribution has been moſt frequently adhered to in the imitation handkerchiefs. The ſpots are ſometimes round, ſometimes ſquare, and ſometimes, though more rarely, triangular. Previous to the diſcovery and introduction of the diſcharging proceſs, as applied to this manufacture, many imitations of the Bandanas had been made by the common mode of calico-printing. But the colours of the printed handkerchiefs,

handkerchiefs, beſides being leſs brilliant at firſt, were found to fade ſo ſoon, that the diſcharged ones do already, in a great meaſure, and will probably very ſoon entirely, ſuperſede them.

The engine employed is a very ſtrong preſs, the whole framing of which is generally of caſt iron. In conſtructing this preſs, it is abſolutely neceſſary that every part ſhould be ſo ſtrong, as to bear a very great preſſure without yielding in any part. A ground plan, and tranſverſe elevated ſection of it, are given in *figs.* 3. and 4. *Plate* VIII. *Miſcellany.*

The pattern to be formed is cut upon two flat plates, which exactly correſpond. They are uſually of caſt iron, and the lower plate is faced with copper, or ſome metal which will both receive a fine poliſh, and reſiſt, to a great degree, the corroſive power of the diſcharging liquor, which is compoſed of a preparation of the oxy-muriate of lime diluted with water. In the under plate, which muſt be perfectly ſmooth and level, a hole is cut for every ſpot which is to be diſcharged. In the upper plate, or cover of the preſs, every ſpot is formed by a hollow tube of braſs or copper, which is tightly driven into a hole formed in the plate, and cemented with a compoſition of white lead and oil, or any other cement, which will prevent the diſcharging liquor from eſcaping by any other paſſage than thoſe through the perforated tubes.

In the ground plan *(fig* 3.), little more of the preſs will be ſeen than the upper ſurface of the cover, which is diſtinguiſhed by the letters A, A, A, A, placed at each corner. About the upper plate or cover is a rim to prevent the diſcharging liquor from running off, which is diſtinguiſhed by the letters B, B, B, B.

At each corner of the plate is a round hole, working upon a pin faſtened in the under plate or ſole of the preſs, to guide the bottoms of the perforated tubes perpendicularly over the holes in the lower plate. Beſides theſe guides, there are two notches C, C, which graſp the upright pillars D, D, and thus the upper plate, when riſing and ſinking, is guided in ſix different places. The elevation and depreſſion of the cover is effected by turning the ſcrew E. The form of the upper and under plates, and the pattern being repreſented by *fig.* 3, the remaining parts of the preſs will be more clearly ſeen by referring to *fig.* 4, which is a tranſverſe elevated ſection of the preſs, cut in the direction of the dotted line F F, *fig.* 3.

The letters of reference in *fig.* 4, are the ſame for each part, as in *fig.* 3, but ſome parts are diſtinctly ſeen in the latter, which do not appear in the former, and theſe are diſtinguiſhed by additional letters. As in *fig.* 3, A A repreſent the upper plate or cover of the preſs. The rims are ſhewn by the letters B, B. The notches which graſp the upright pillars are marked C, C, and the pillars D, D. The ſcrew which raiſes and ſinks the cover of the preſs is diſtinguiſhed by the letter E. Between the pillars D, D, is an arch of iron H H, in the centre of which is a box I, containing a female ſcrew for working the ſcrew E. The lower part of the ſcrew E revolves in the ſocket G fixed to the cover of the preſs, and thus raiſes or ſinks it as may be neceſſary. Upon the ſcrew E, is fixed a wheel K K, through the arms of which is put the lever uſed for ſcrewing down and raiſing the cover, as in other large preſſes. The ſole or bottom of the preſs is diſtinguiſhed by the letters L, L. It is placed exactly in a horizontal direction, and is ſupported by ſix ſtrong iron perpendicular legs, namely, one at each corner, and the lower parts of the pillars D, D, in the middle. Between the cover and bottom, the cloth to be diſcharged is placed at M M.

The mechanical part of this proceſs is, in almoſt every reſpect, entirely ſimilar to that uſed by cloth dreſſers, bookbinders, and many other tradeſmen who employ ſtrong ſcrew preſſes. To enſure the accuracy of its operation, correctneſs of workmanſhip, and ſtrength, are all that are neceſſary, and theſe are indiſpenſable. The preſs muſt be fixed, ſo that both the cover and bottom may be horizontal planes. The bottom muſt be perfectly level, and the perforated tubes in the cover muſt all exactly touch the bottom, with equal preſſure. The perforation of the tubes muſt alſo correſpond exactly with the holes or apertures in the bottom, and the guides muſt be fitted to work freely, but at the ſame time to prevent any aberration of the cover in riſing or ſinking. From the great preſſure neceſſary when the cover is ſcrewed down, great care ought to be taken that the whole of the ſupporters of the preſs be exactly perpendicular, and that the preſs, when properly placed, ſhould be ſtrongly ſecured.

The apparatus being well made and properly ſecured, the proceſs of manufacture is remarkably ſimple. The cloth is woven of the natural colour of the cotton wool, and in this particular the manufacture, beſides the beauty of its appearance, poſſeſſes a decided preference, in point of economy, over the Pullicate handkerchiefs, and other imitations of the Indian manufacture, where the pattern is produced in the loom, and the ſtuff previouſly dyed in the ſtate of yarn. Whatever care has been taken to prevent the tedious and repeated proceſſes, which are uſed in the dyeing of Turkey red, from injuring the yarn, every perſon, at all converſant with the manufacture of coloured yarn, will be ſenſible that all the ſubſequent ſtages of the operation of forming it into cloth are much impeded by the preparatory change which it has undergone in the dyers' hands; and from the nature of the proceſs this perhaps applies to no colour in ſo great a degree as to Turkey red. It follows that the wages given to winders, warpers, and weavers, muſt be raiſed in proportion to the impediments which they have to encounter, and to the ſmaller quantity of cloth which their exertions can of conſequence produce. Beſides this, all handkerchiefs ornamented in the loom, are confined to what is called *checking;* and all the various colours muſt be interwoven either parallel or at right angles to each other, unleſs very complicated and conſequently expenſive mounting be uſed. The time conſumed in changing the colours of the woof alſo impedes, in no ſmall degree, the ſpeed of the operation; and thus both the ſtate and nature of his materials, and the mechanical operation neceſſary to accompliſh his purpoſe, tend at the ſame time to enhance the wages of the weaver, in proportion to the quantity of cloth which is the product of his labour.

But as the imitation Bandanas are woven perfectly plain, the ſame as calicoes, cambrics, and other ſtout fabrics, no impediment of this kind occurs, and the whole labour and expence are in the ſubſequent proceſs, and the ſum ſunk in procuring the preſs.

After the cloth is woven, it is cleared from impurities, and dyed Turkey red, exactly in the ſame way as yarn is dyed. When the colour is to be diſcharged, the cloth is neatly folded in ſquares, of about 10 or 12 folds, and laid upon the ſole or under plate of the preſs, the cover being previouſly elevated by means of the ſcrew and wheel. When the cloth has been properly diſpoſed, as at M M, the cover is brought down in contact with its upper ſurface, and a lever being applied to the ſcrew and wheel, the upper and under plates are firmly ſcrewed together, the cloth being between them. The under part of each of the perforated tubes now preſſes hard upon the upper ſurface of the cloth, and being perpendicularly over the holes in the under plate, no part of the diſcharging liquor can eſcape, excepting through

through the apertures which form the pattern. Theſe apertures are diſtinguiſhed in the ſection, *fig.* 4, by the numbers 1 to 8. The preſs being ſcrewed down, the diſcharging liquor is poured upon the cover, and being confined by the rim paſſes through the apertures, and diſcharges the colour from thoſe parts of the cloth which it paſſes through, being prevented from ſpreading upon any other part by the power of the ſcrew. The diſcharging liquor is received into a trough placed under the lower plate of the preſs, and diſtinguiſhed by the letter N. From this trough it is conveyed, by a ſpout, into veſſels placed to receive it, and preſerved; for although it loſes much of its chemical quality in paſſing through the cloth and diſcharging the colour, it retains ſo much as ſtill to be of ſervice in many of the inferior operations of clearing and whitening of cloth. The diſcharge of the colour is effected by the action of the liquor in about eight or ten minutes. When the liquor has paſſed through, the cover of the preſs is raiſed, the cloth is taken out, and another piece being ſubſtituted, the operation goes on as before.

When two induſtrious perſons are employed, for the purpoſes of folding the cloth, working the preſs, and applying the liquor, it is calculated, that the operation, for one piece of 12 handkerchiefs, occupies about 15 minutes; conſequently, two perſons can diſcharge 48 or 50 dozens of handkerchiefs in one day of 12 working hours.

The operation requires only care and attention; for if the preſs be properly conſtructed, nothing more is required than to fold the handkerchiefs neatly, to lay them ſquare upon the under plate of the preſs, and to be careful that the cover is tightly ſcrewed down before the liquor is applied. When the handkerchiefs are taken from the preſs, the diſcharged ſpots do not appear white, but of a dull ſtraw colour. The common operation of clearing, however, very ſoon gives a pure white to the ſpots, and adds brilliancy to the Turkey red ground. Thoſe who have been longeſt in the habit of working theſe preſſes, conſider a moſt important point to be, attention to the cement which is put where the perforated tubes are connected with the cover of the preſs. This certainly requires frequent and careful examination; for if any of the liquor is allowed to eſcape here, the ground of the handkerchiefs will be materially injured by its operation upon the colour. As the invention is recent, and the ſtudy of practical chemiſtry rapidly advancing, it is not improbable that ſome compoſition of ſuperior efficacy, for this purpoſe, may ſoon be diſcovered. The cement uſed anſwers the purpoſe tolerably well, but requires great attention on the part of the perſon to whom the charge of the preſs is entruſted.

It has been already obſerved, that the chemical liquor generally employed is a ſolution of the oxymuriate of lime.

The method of preparing this liquor was diſcovered and firſt introduced into practice by Charles Tennant, eſq. St. Rollocks, near Glaſgow; and is, at preſent, univerſally uſed by thoſe engaged in the manufactory. The following remarks, upon its practical application, have been obligingly communicated to the writer of this article by that gentleman, which he will copy in his own words:—

"Agreeable to my experiments, a ſolution of the oxymuriate of lime, of 1.010 ſpecific gravity, decompoſed by $\frac{1}{100}$th part of its weight of ſulphuric acid, of 1.846 ſpecific gravity (the uſual quality of marketable ore), is the moſt advantageous preparation for diſcharging Turkey red; and what, I believe, is in pretty general uſe with the trade in this quarter.

"As the oxymuriatic acid is but little ſoluble in water, when diſengaged from its combination with the lime, the ſooner it is uſed, after its ſeparation by the ſulphuric acid, the better; and this is done by ſimply filling the types with the ſolution, and allowing it to remain in them for ſo many minutes as proper, until the diſcharge is effected.

"When the diſcharge is completed, the acid liquor muſt be carefully waſhed out of the types previous to their being removed from their hold of the cloth."

It is hardly neceſſary to obſerve, that the word types, uſed by Mr. Tennant, refers to the perforated tubes fixed in the cover of the preſs, and previouſly deſcribed in the mechanical part of this article.

Some alteration in the conſtruction of the preſſes has very recently been introduced into ſome of the manufactories. The chief difference from the preſs repreſented, conſiſts in preſſing down the cover by a great weight, inſtead of the action of the ſcrew. Water has been uſed to give this weight, and is raiſed into a trough upon the cover by means of a forcing pump, when the preſſure is to take place. This may certainly preſs more equally over the whole ſurface of the cover than a ſcrew, which acts only upon one point, and in this particular may be an improvement. Few of theſe preſſes have, as yet, been uſed; but thoſe which have, are ſaid to anſwer very well.

DISCIPLE, from *diſco*, I learn, one who learns any thing from another. Thus the followers of any teacher, philoſopher, &c. are called diſciples. In the Chriſtian ſenſe, they were the followers of Jeſus Chriſt, in general; but in a more reſtrained ſenſe, the diſciples denote thoſe alone who were the immediate followers and attendants on his perſon; of which there were ſeventy, or ſeventy-two. The names diſciple and apoſtle are often ſynonymouſly uſed in the goſpel hiſtory; but ſometimes the apoſtles are diſtinguiſhed from diſciples, as perſons ſelected from them, to be the principal miniſters of his religion; of theſe there were only twelve. (See APOSTLE.) The Latins keep the feſtival of the ſeventy, or ſeventy-two diſciples, on July 15; and the Greeks on January 4.

DISCIPLINE primarily ſignifies inſtruction and government; but the word is figuratively applied to a ſtated method of living, according to the rules of ſome profeſſion.

We ſay the military diſcipline, the eccleſiaſtic or church diſcipline, the regular or monaſtic diſcipline, &c.

We do not ſay civil diſcipline, but inſtead thereof policy.

DISCIPLINE is alſo uſed in a peculiar ſenſe for the chaſtiſement, or bodily puniſhment, inflicted on a religious, who has been caught delinquent; or even for that which the religious voluntarily undergo, or inflict on themſelves, by way of mortification.

Among all the auſterities practiſed by the ancient monks and ſolitaries, Dupin obſerves, there is no mention made of diſcipline; in effect, it does not appear to have been in uſe in antiquity, unleſs to puniſh the monks who had been taken tripping.

It is commonly ſaid that St. Dominic, and Peter Damian, firſt introduced the uſe of diſcipline; but F. Mabillon notes, that Guy, abbot of Pompoſa, and others, had practiſed it before them. It is pretty certain, the practice was firſt eſtabliſhed in the eleventh century, with deſign to redeem the penances the canons impoſed on divers offences; and at length they came not only to redeem for themſelves, but alſo for others. See F. MABILLON.

DISCIPLINE is alſo frequently uſed for the inſtrument wherewith a monk chaſtiſes, or mortifies himſelf; which is uſually made of ropes, knotted hair, or twiſted parchment; ſometimes of broken rods. St. Jerom is painted with diſciplines of iron chains, armed with ſpur-rowels, &c. See FLAGELLATION.

DISICPLINE,

DISCIPLINE, *Book of*, in the *History of the Church of Scotland*, is a common order, drawn up by the assembly of ministers in 1650, for the reformation and uniformity to be observed in the discipline and policy of the church. In this book the government of the church by prelates is set aside, church-sessions are established, the superstitious observation of fast-days and saints' days is condemned, and other regulations for the government of the church are determined. This book was approved by the privy-council, and is called the first book of discipline.

The puritans, in the reign of queen Elizabeth, who were zealous in their endeavours to effect a reformation of discipline in the national establishment, held in high estimation "a book of discipline," entitled "Disciplina ecclesiæ sacra ex Dei verbo descripta," *i.e.* the holy discipline of the church described in the word of God. This work was drawn up in Latin by Mr. Travers, a fellow of Trinity college, Cambridge; and printed at Geneva about the year 1574; and afterwards revised, corrected, and improved by Mr. Cartwright and other learned ministers at their synods. It was translated into English in the year 1584, and designed to be published for general use; but it was seized at the press, and all the copies were ordered to be burnt, as factious and seditious. A copy of it was found in Mr. Cartwright's study after his death, and reprinted in the year 1644, under a new title, *viz.* "A directory of government, &c. practised by the first non-conformists, in the days of queen Elizabeth, &c." This book contained those alterations in discipline, &c. for which the puritans contended. In the year 1586, more than 500 ministers, all beneficed in the church of England, useful preachers, of unblemished character, subscribed, with some exceptions, or declared their approbation of this book of discipline.

DISCIPLINE, *military*, denotes the exercise of those laws that are established for regulating the conduct of military men.

DISCIPLINE, *marine*, signifies the training up soldiers for sea-service, in such exercises and manœuvres as can be performed on board ships of war at sea.

DISCLAIMER, in *Law*, a plea, containing an express denial, renouncing, or disclaiming, of a thing alleged.

As if a tenant sue a replevin upon a distress taken by the lord, and the lord avow the taking, saying, that he holds of him as his lord, and that he distrained for rent not paid, or service not performed; then the tenant, denying to hold of such lord, is said to disclaim; and the lord proving the tenant to hold of him, on a writ of right *sur disclaimer* brought, the tenant loses his land. This disclaimer by a tenant is considered as a civil crime, and punished accordingly, by forfeiture of lands to the lord, on reasons most apparently feudal. (Finch. 270, 271.) Thus also, if in any court of record the particular tenant does any act which amounts to a virtual disclaimer: if he claims any greater estate than was granted him at the first infeodation, or takes upon himself those rights which belong only to tenants of a superior class (Co. Litt. 252.); if he affirms the reversion to be in a stranger, by accepting his fine, attorning as his tenant, collusive pleading and the like (ibid. 253); such a behaviour amounts to a forfeiture of his particular estate. (Blackst. Com. vol. ii. and iii.)

When a tenant hath disclaimed, upon action brought against him, he shall not have restitution on writ of error, &c. against his own act; but is barred of his right to the land disclaimed. (8 Rep. 62.) But a verbal disclaimer shall not take place against a deed of lands; nor shall the disclaimer of a wife during the coverture bar her entry on her lands. (3 Rep. 26.) Baron and feme may disclaim for the wife; though if the husband hath nothing but in right of his wife, he cannot disclaim. (2 Danv. Abr. 569.) A person who cannot lose the thing perpetually in which he disclaims, shall not be permitted to disclaim; a bishop, &c. may not disclaim, because he cannot divest the right out of the church; although in a *quo warranto*, at the suit of the king against a bishop or others for franchises and liberties, &c. if the bishop, &c. disclaims them, this shall bind the successors. (Co. Litt. 102, 103.) If a man be vouched because of a reversion on a lease made by himself, he cannot disclaim; but an heir may disclaim, being vouched upon a lease made by his ancestor. (2 Danv. 569.) It is said not to be necessary, that the writ of right, *sur disclaimer*, should be brought against the person that disclaims; for if it be only against him that is found tenant of the land, though he be a stranger, it is not material. (2 Danv. 570.)

By statute 21 Jac. I. c. 16. s. 5, in all actions of trespass *quare clausum fregit*, in which the defendant shall disclaim any title to the land, and the trespass be by negligence, or involuntary, the defendant shall be admitted to plead a disclaimer, and that the trespass was by negligence, or involuntary, and a tender of sufficient amends before the action brought; and if the issue be found for the defendant, or the plaintiff be non-suited, the plaintiff shall be barred from the said action, and all suits concerning the same. Besides these disclaimers by tenants of lands, there are other disclaimers; thus, a man, denying himself to be of the blood, or kindred of another, in his plea, is said to disclaim his blood (F. N. B. 102.) If a man arraigned of felony, disclaim goods; being cleared, he loses them. (Standf. P. C. 186.)

Thus, likewise, in chancery, if a defendant by his answer renounces having any interest in the thing in question, this is a disclaimer: to which may be added, a disclaimer by renouncing an executorship of a will, or the right to an administration.

DISCLAMATION, in *Scots Law*, is that casualty by which a vassal forfeits his whole feu to his superior, if he disowns, or disclaims him, without ground, as to any part of it.

DISCLOSED, a term used for chickens, or hawks, newly hatched; also for buds, or flowers, just blown.

DISCOBOLI, Δισκοβολοι, from δισκος, and βαλλω, *I throw*, among the *Ancients*, an appellation given to those who gained the victory at the discus. See DISCUS.

DISCOID FLOWERS, in *Botany*, are such compound flowers as, having no radius, consist of regular tubular florets, crowded and parallel, and all together forming a surface nearly flat, as in *Santolina*, or exactly conical, as in *Spilanthus*. The same term is used, even though marginal florets be present, provided they are small and inconspicuous, as in *Artemisia*, *Tanacetum*, &c.

DISCOIDES FIBULA, in *Natural History*, the name of a genus of the echinodermata, or sea hedge-hogs; the periphery of the base of these is exactly round, and the body of a convexo-concave figure. The principal species of this genus is the subuclus, which has sometimes a rosaceous top, the lines being very neat and elegant, sometimes a plain and smooth top; sometimes it is all over covered with extremely minute and fine striæ, and sometimes it is much flatter than at others. Klein's Echinoderm.

DISCONTINUANCE, an interruption, intermission, or cessation, of the course of a thing; as, discontinuance of possession, of a plea, process, &c.

Discontinuance, as to real property, is an injury, which consists in keeping out the true owner of an estate, by a

tenant

tenant whoſe entry was at firſt lawful, but who wrongfully detains the poſſeſſion afterwards. This happens, when he, who hath an eſtate-tail, maketh a larger eſtate of the land than the law allows him to do (Finch. L. 190.); in which caſe, the eſtate is good, ſo far as his power extends who made it, and no farther. As if tenant in tail makes a feoffment in fee-ſimple, or for the life of the feoffee, or in tail: all which are beyond his power to make, for that by the common law extends no farther than to make a leaſe for his own life; in ſuch caſes, the entry of the feoffee is lawful during the life of the feoffor; but if he retains the poſſeſſion after the death of the feoffor, it is an injury, which is termed a *diſcontinuance*:—the ancient legal eſtate, which ought to have ſurvived to the heir in tail, being gone, or, at leaſt, ſuſpended, and for a while diſcontinued. For, in this caſe, on the death of the alienors, neither the heir in tail, nor they in remainder, or reverſion, expectant on the determination of the eſtate-tail, can enter on and poſſeſs the lands ſo alienated. Alſo, by the common law, the alienation of an huſband who was ſeized in the right of his wife, worked a diſcontinuance of the wife's eſtate; till the ſtatute 32 Hen. VIII. c. 28. provided, that no act by the huſband alone ſhall work a diſcontinuance of, or prejudice, the inheritance or freeho'd of the wife: but that, after his death, ſhe or her heirs may enter on the lands in queſtion. Formerly alſo, if an alienation was made by a ſole corporation, as a biſhop or dean, without conſent of the chapter, this was a diſcontinuance, (F. N. B. 194.) But this is antiquated by the diſabling ſtatutes of 1 Eliz. c. 19, and 13 Eliz. c. 10; which declare all ſuch alienations abſolutely void, *ab initio*; and, therefore, at preſent no diſcontinuance can thereby be occaſioned. Blackſt. Comm. book iii. A diſcontinuance may be in five ways, *viz.* by feoffment, fine, recovery, releaſe, and confirmation with warranty. (1 Rep. 44.) A diſcontinuance may be defeated, where the eſtate that worked it is defeated; as if a huſband make a feoffment of the wife's land upon condition; and after his death, his heir enters on the feoffee for the condition broken; now the diſcontinuance is defeated, and the feme may enter upon the heir. Co. Litt. 336.

DISCONTINUANCE *of Plea*, is when divers things ſhould be pleaded to in a ſuit of action, and ſome are omitted, If a defendant's plea anſwers to part only, it is a diſcontinuance; and the plaintiff may take judgment by *nil dicit*, for that which is not anſwered: but if the plaintiff plead over, the whole action is diſcontinued. 1 Nelſ. Abr. 660, 661. 1 Salk. 139.

If a juſtice-ſeat be diſcontinued by the not coming of the juſtices, the king commonly renews the ſame by his writ, &c.

DISCONTINUANCE *of Proceſs* is ſomewhat ſimilar to a non-ſuit; for, when a plaintiff leaves a chaſm in the proceedings of his cauſe, as by not continuing the proceſs regularly from day to day, and time to time, as he ought to do, the ſuit is diſcontinued, and the defendant is no longer bound to attend; but the plaintiff muſt begin again, by ſuing out a new original, uſually paying coſts to his antagoniſt. Anciently, by demiſe of the king, all ſuits depending in his court were at once diſcontinued, and the plaintiff was obliged to renew the proceſs, by ſuing out a freſh writ from the ſucceſſor; the virtue of the former writ being totally gone, and the defendant no longer bound to attend in conſequence thereof; but, to prevent the expence, as well as the delay attending this rule of law, the ſtatute 1 Edw. VI. c. 7, enacts, that, by the death of the king, no action ſhall be diſcontinued; but all proceedings ſhall ſtand good, as if the ſame king had been living. The diſcontinuance of an action is not perfect till it is entered on the roll, when it is of record. (Cro. Car. 236.) The plaintiff cannot diſcontinue his action after a demurrer joined, and entered; or, after a verdict, or writ of inquiry, without leave of the court. (Cro. Jac. 35. 1 Lil. Abr. 473.) It has been ruled, upon a motion to diſcontinue, that the court may give leave after a ſpecial verdict, which is not complete and final; but never after a general verdict. (1 Salk. 178. Hardw. 200, 201.) After iſſue and a verdict, the plaintiff cannot diſcontinue without conſent of the defendant; for, if the plaintiff will not enter up judgment, the defendant may. (Salk. 178.) After demurrer argued and allowed, diſcontinuance may be allowed on payment of coſts. 3 Lev. 440.

Diſcontinuance of proceſs is helped at common law by appearance; and by ſtat. 32 Hen. VIII. c. 30. all diſcontinuances, miſcontinuances which continue the ſuit by improper proceſs, or by giving the party an illegal day and negligence therein, are cured after verdict. See AMENDMENT.

DISCORD, in *Muſic*, is a ſound which, when ſtruck with another in counterpoint, is diſagreable to the ear. See COUNTERPOINT.

What renders diſcords diſagreeable to the ear, is their always jarring, and we may ſay warring with each other, and arriving at the ſenſorium like two diſtinct ſounds, though ſtruck or ſounded at the ſame inſtant.

Sometimes the interval is called a diſcord, and ſometimes each of the ſounds that form the diſcordant interval. But though any ſounds that diſagree may be termed diſcords, that title more particularly belongs to that of the two which is foreign to the harmony of the baſe.

There is in nature an infinity of diſcords; but though in muſic none are admitted, except ſuch as belong to the genus and key in which the piece is compoſed, or into which it may modulate, and theſe are ſpecified in the rules of compoſition.—What then are theſe rules? Have they any foundation in nature, or are they purely arbitrary? Let us examine. The phyſical principle of harmony reſides in the common chord, or the harmonies of a ſingle ſound. All concords are derived from that ſource, and it is nature that furniſhes this chord. But that is not the caſe with diſcords, at leaſt with ſuch as are admitted in muſic. We perceive, indeed, how they are generated; by the progreſſion of conſonant intervals and their differences; but we perceive not the phyſical cauſe which warrants our uſe of them in the compoſition of harmony. Nature points out the origin of ſuch harmony as is grateful to our ears, and when it becomes otherwiſe, we ſtop.

There is a diſcord in the 7th diviſion of every ſtring. It is not indeed a true 7th; but it is more like that diſcord than any thing elſe, except the extreme ſharp 6th; and it is ſo equivocal, that it will ſerve for either: ſuppoſe C the fundamental, the 7th diviſion of the ſtring will ſerve for B ♭ or A ♯, for both which it ſerves on keyed-inſtruments.

Now, as nature gives this kind of 7th to every fundamental baſe, if we join the 7th with the 8th in practice, ſuppoſe the key to be G, we have the chord of the minor 7th to G, $\frac{6}{5}$ to B, and $\frac{4}{3}$ to D, diſcords which nature has pointed out, if not correctly produced. F and G are likewiſe the two 5ths, or 4th and 5th of the key of C; the perfect chords of which therefore furniſh, with that of the key note C, the eſſential harmony to that and every other key.

Rouſſeau, therefore, not being able to find the origin of diſcord in nature, or in Rameau's ſyſtem, has treated it as a

mechanical operation. But, are we never to uſe the minor modes which afford us ſuch exquiſite pleaſure in plaintive and pathetic ſtrains, becauſe its origin is out of our reach? Are we never to ſmell at a roſe, becauſe we cannot account for its being more fragrant than the taudry poppy? And, becauſe in comparing ſucceſſively the ſounds of the diatonic ſcale, major and minor, with the fundamental, Rouſſeau, and ſome other theoriſts, find only two diſcords, the 2d and the 7th, are we to uſe no others?

We were not quite ſatisfied with the article *Diſcord* in the laſt fol. from Graſſineau and Malcolm, and tried to make the matter more clear, pleaſant, and intelligible from the ingenuity and eloquence of Rouſſeau, who, in his Muſical Dictionary, has given us an article, or rather a diſſertation on the ſubject, of 10 or 12 pages; but it contains nothing but a dry confutation of Rameau's origin of the minor mode, which was never favourably received or adopted, even by his moſt zealous diſciples, and has now been long forgotten.

We ſhall therefore attempt no new phyſical or metaphyſical diſcoveries concerning diſcord; but ſhall conclude this article by informing young muſical ſtudents, that though Rouſſeau has reduced all diſcords to the 2d, or at moſt to that and the 7th, which is but the 2d inverted; we think it right to inform them, that the 4th and the 9th are ſtill regarded as diſcords by many who will expect them to be regularly prepared and reſolved, as well as the 5th when made a diſcord by the 6th, and the 3d by the 4th; ſo that it may be imprudent, and attended with ſome inconvenience, if they are not ſtudied and practiſed, whatever they may be called; and we ſhall only aſk reformers of the old ſyſtem of harmony, if the 3d made a diſcord by the 4th, the 4th by the 5th, the 5th by the 6th, and the 9th by the $\frac{5}{3}$, are *not* diſcords, what *are* they?

See the regular preparation of all practical diſcords. COUNTERPOINT, *Pl.* XIV. XV. XVI. and paſſing notes added to the latter.

Diſcords are of two kinds: thoſe that are regularly prepared and reſolved, and paſſing notes, in which no harmony is given.

In moving baſes, or diviſions in the treble, all the notes not to be found in the chord on which the paſſage is built, are paſſing notes.

Padre Martini has given in ſix bars (Saggio di contrap.) all the regular diſcords, with their preparations and reſolutions. See examples of Counterpoint in Types.

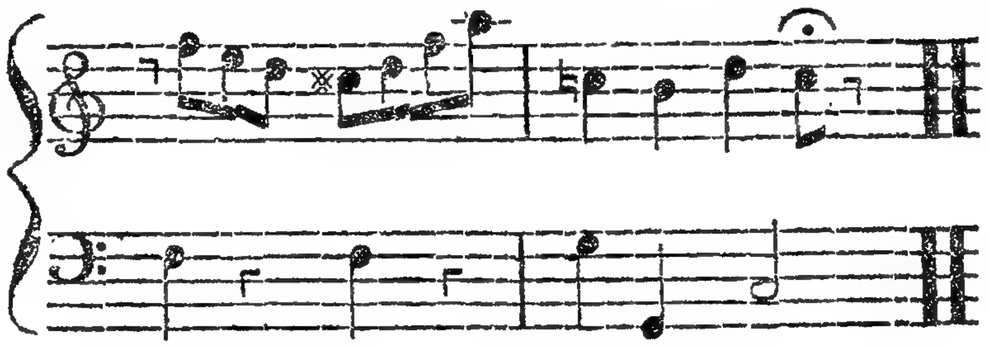
Diſcords ſeem to have originated from *appoggiaturas*, or embelliſhments of a treble part.

Sevenths reſolved into 6ths, are appoggiaturas; as are the baſes carrying 2ds.

As melody quitting Canto Fermo, and plain counterpoint, began to receive ornaments, appoggiaturas ſeem to have been the firſt that were received in harmony. The 4th made a diſcord by the 5th at a cloſe, is the firſt that appears in the moſt ancient counterpoint that has been preſerved.

Man has been defined by the French, *animal d'habitude*, and ſaid by the Engliſh to be "a bundle of prejudices." And melody in muſic may be ſaid to conſiſt of a bundle of appoggiaturas; firſt introduced by ſingers, and for which it afterwards became the buſineſs of compoſers to find harmony.

Great relaxation has taken place of late in the preparation of diſcords; it uſed to be an inviolate rule never to jump to any diſcord except the 7th; but Berthoven, op. 14. jumps to the 9th. We have formerly ſaid, that the preparation of diſcords in vocal muſic was probably eſtabliſhed as a rule in favour of bad ſingers, who were uncertain of hitting them right *per ſaltum*. But very pleaſing and pathetic effects are to be produced by unprepared diſcords. As all good taſte in muſic originates from good ſinging, ſo good ſingers were the firſt to hazard, at a cloſe, an unprepared 9th, as in the following example:



Old rules told us, that double diſcords muſt be doubly prepared and reſolved. See Muſic plates.

Rouſſeau has given, in *Pl.* K. of his Dict. de Muſ. *fig.* 1. two diatonic ſcales, one, the natural ſcale, in conſtant and univerſal uſe; the other he calls the ſcale of *Aliquots*, in which are introduced two new characters, for which we have no names or inſtruments by which they can be expreſſed: theſe are the falſe notes of the French horn and trumpet, which a few modern theoriſts want to perſuade us, in ſpite of our ſenſes, are the true harmonies of nature. But they have never yet been admitted in an orcheſtra, or written in a muſical compoſition. We give the Greek enharmonic ſcale, as a curioſity; but of which we can make no uſe in counterpoint; as we have no fundamental baſe for quarter tones. We have but two genera, one diatonic, and one chromatic, for the eye; when theſe are to be corrected, the key, and the ear of the performer, muſt determine.

The new equivocal character given by Rouſſeau and Kirnberger, for what are generally called the falſe notes, or 4th and 6th of the French horn and trumpet thus: 8 ſomething reſembling a double B b.

DISCORD, *apple of*, *pomum diſcordiæ*, a phraſe uſed to ſignify the ſubject, or occaſion of ſome miſunderſtanding in a ſociety.

DISCORD *goddeſs of*, in *Mythology*, called alſo *Até*, and *Eris*, is deſcribed by Ariſtides as having fiery eyes, a pale countenance, and livid lips, and as wearing a dagger in her boſom. This was the goddeſs, who is ſaid, at the marriage of Peleus and Thetis, to have thrown the golden apple, on which was written, "To the faireſt," which occaſioned a contention between the goddeſſes Juno, Minerva, and Venus; each pretending a title to the apple.

DISCORDANT, *out of tune*, falſe concords, or diſcords, *intonazioni perfidi*, in melody and harmony.

DISCOVERT, in *Law*, denotes an unmarried woman.

DISCOVERY, the act of revealing or diſcloſing any matter by the defendant, in his anſwer to a bill filed againſt him in a court of equity.

The courts of equity may in many caſes compel a diſcovery, with a view of ſubſerving the general adminiſtration of juſtice. But if a bill is brought to aid, by a diſcovery, the proſecution or defence of any proceeding "not merely civil," in any other court, as an indictment or information, a court of equity will not exerciſe its juriſdiction to compel a diſcovery, and the defendant may demur. (2 Vez. 398.) And in the caſe of ſuits merely civil, in a court of ordinary juriſdiction, if that court can itſelf compel the diſcovery required, a court of equity will not interpoſe. (1 Atk. 288. 1 Vez. 205. 2 Vez. 451.) The ſituation of a defendant may render it improper for a court of equity to compel a diſcovery, either, 1. becauſe the diſcovery may ſubject the defendant to pains and penalties, or to ſome forfeiture; or, 2. it may hazard

hazard his title in a caſe where in conſcience he has an equal right with the perſon requiring the diſcovery; though that right may not be inveſted with a perfect title. It is a general rule that no one is bound to anſwer ſo as to ſubject himſelf to puniſhment, in whatever manner that puniſhment may ariſe, ot whatever may be its nature. But if the plaintiff alone is entitled to the penalties, and expreſsly waves them by his bill, the defendant ſhall be compelled to make the diſcovery; for it can no longer ſubject him to a penalty. (1 Vern. 60.)

DISCOVERY *of accomplices* is provided in the caſes of coining, robbery, burglary, houſe-breaking, horſe-ſtealing, and larceny, to the value of five ſhillings, from ſhops, warehouſes, ſtables, and coach-houſes, by ſtatutes 4 and 5 W. & M. c. 8. 6 and 7 W. III. c. 17. and 11 W. III. c. 23. and 5 Anne, c. 31. which enact, that if any ſuch felon, being out of priſon, ſhall diſcover two or more perſons, who have committed the like felonies, ſo that they may be convicted, he ſhall in caſe of burglary or houſe-breaking, receive a reward of 40l. and in general be entitled to a pardon of all capital offences, excepting only murder and treaſon; and of them alſo, in caſe of coining. And if any ſuch perſon having feloniouſly ſtolen any lead, iron, or other metals, ſhall diſcover and convict two offenders of having illegally bought or received the ſame, he ſhall, by ſtat. 29 Geo. II. c. 30. be pardoned for all ſuch felonies committed before ſuch diſcovery.

It hath alſo been uſual for the juſtices of the peace, by whom any perſons charged with felony are committed to gaol, to admit ſome one of their accomplices to become a witneſs (or, as it is generally termed, king's evidence) againſt his fellows; upon an implied confidence which the juſtices of gaol-delivery have uſually countenanced and adopted, that if ſuch an accomplice make a full and complete diſcovery of that and all other felonies to which he is examined by the magiſtrate, and afterwards give his evidence without prevarication or fraud, he ſhall not himſelf be preſented for that or any other previous offence of the ſame degree.

DISCOVERY by *bankrupt*. See BANKRUPT.

DISCOVERY in *Dramatic Poetry*, a manner of unravelling a plot or fable, very frequent in tragedies, comedies, and romances; wherein, by ſome unforeſeen accident, a diſcovery is made of the name, fortuue, quality, and other circumſtances of a principal perſon, which were before unknown. See CATASTROPHE.

A diſcovery ſhould never be in vain, by leaving thoſe who thus diſcovered one another in the ſame ſituation and ſentiments they were in before: in effect thoſe diſcoveries, which are immediately followed by a peripetia, or change of fortune of ſome principal character, whereon the unravelling depends, are always the moſt beautiful.

One of the fineſt diſcoveries ever brought upon the ſtage, is that of Oedipus in Sophocles; for the minute he finds himſelf the ſon of that Jocaſta who was then his wife, he becomes, of the moſt happy, the moſt miſerable of all men.

There are three ſorts of diſcoveries: the firſt by certain marks of the body, either natural or accidental: ſuch is that of Ulyſſes, who having received a wound in the thigh by a boar before the Trojan war, is diſcovered by the old nurſe, upon waſhing his legs after his return home incognito.

The ſecond by tokens: as the caſket of things, which the prieſts found with Ion when he was expoſed, diſcovers Creuſa, whom he was going to kill, to be his mother.

The third is made by remembrance: that is, when the ſight or hearing of any thing occaſions us to recollect our misfortunes. Thus, when Ulyſſes heard Demodocus ſing his actions at Troy, the memory of them ſtruck him, and drew tears from his eyes, which diſcovered him to Alcinous.

But the fineſt ſort is, that which ariſes from the ſubject, or incidents of the fable; as that of Oedipus from his exceſſive curioſity, and the letter that Iphigenia ſent by Pylades. See TRAGEDY.

DISCOUNT, in *Commerce*, an allowance made for the immediate advance of money which is not due till the end of a certain period, as on a promiſſory note, or bill of exchange, which has two or three months to run from the time when it is diſcounted.

The true diſcount of any ſum is, ſo much as being deducted, will leave a ſum which, in the time diſcounted for, will, at intereſt, amount to the original principal. Thus, one pound, diſcounted for one year, is equal to that ſum which, at the given rate, will, in one year, amount to one pound, and the diſcount is the difference between this ſum and one pound: now, as $1 + r : 1 :: 1 : \frac{1}{1+r}$, the ſum which, in one year will amount to one pound, and, conſequently, $1 - \frac{1}{1+r} = \frac{r}{1+r}$ is the diſcount of one pound for one year. On this principle, the diſcount of one pound, for one year, at the ſeveral rates following, is found to be,

At 2 *per cent.* - -	.019607843137
3 - - -	.029126213592
4 - - -	.038461538462
5 - - -	.047619047619
6 - - -	.056603773585
7 - - -	.065420560748
8 - - -	.074074074074
9 - - -	.082568807339
10 - - -	.090909090909

The diſcount of one pound, for one year, multiplied by any ſum, gives the diſcount of that ſum for one year: thus, to find the diſcount of 160*l.* for one year, at 5 *per cent.* .047619 × 160 = 7*l.* 12*s.* 4½*d.*

The diſcount for any number of days is found in the ſame way as the diſcount for one year; for, as one pound, increaſed by its intereſt for any number of days, is to 1*l.*, ſo is 1*l.* to a fourth number, which will be one pound diſcounted for the given days; and this, ſubtracted from one pound, gives the diſcount required: therefore, "divide one pound by one pound, increaſed by its intereſt, and the complement of the quotient is the diſcount required." By this rule, the following diſcounts of 1*l.* are found:

Days.	3 per. Cent.	4 per Cent.	5 per Cent.
1	.00008218	.00010958	.00013697
2	.00016436	.00021913	.00027390
3	.00024651	.00032866	.00041079
4	.00032866	.00043816	.00054765
5	.00041079	.00054765	.00068446
6	.00049291	.00065710	.00082124
7	.00057501	.00070653	.00095798
8	.00065710	.00087594	.00109469
9	.00073918	.00098533	.00123136
10	.00082124	.00109469	.00136799
50	.00409277	.00544959	.00680272
100	.00815217	.01084011	.01351351
200	.01617251	.02144772	.02666667
300	.02406417	.03183024	.03947368

The

The diſcount for any number of days not contained in this table, cannot be found by the addition, or multiplication, of thoſe which are contained in it; for if, from 1*l.*, we ſubtract the diſcount for any number of days, the remainder will be that ſum which, in the ſame number of days, would gain the diſcount ſubtracted; but if, in order to diſcount 1*l.* for double the number of days, we ſubtract twice the former diſcount, the remainder being leſs than before, cannot gain ſo much intereſt, and, therefore, in twice the time cannot gain twice the intereſt which the former ſum gained; and which, being the ſum now ſubtracted, is what ought to be gained to amount again to one pound. A complete table, on the plan of the above, is given in Smart's Tables of Intereſt, but few perſons will find occaſion to refer to it.

The diſcount of any ſum, for any time, is ſo much as will, in the given time, amount to the intereſt of the ſum to be diſcounted; thus, if by retaining 100*l.* for one year, 5*l.* is gained at the end of the year, the proper equivalent to be received for the immediate advance of the ſame is 4*l.* 15*s.* 2½*d*, becauſe this ſum will, at the end of the year, amount to 5*l.*, which is what the 100*l.* would have gained.

Theſe are the true principles of diſcount; but the common mode of diſcounting bills of exchange is, by finding the ſimple intereſt for the time the bill has to run, (including the days of grace,) and deducting ſuch intereſt from the amount of the bill, which gives the ſum to be advanced. This is the method followed by the bank of England, the London bankers, and commercial perſons in general. It enables thoſe who employ their money in diſcounting, to make ſomewhat more than 5 *per cent.* intereſt of it; for a perſon diſcounting 100*l.* for a twelve-month, advances only 95*l.*, by which, at the end of the year, he gains 5*l.*, conſequently, he improves his money, at the rate of 5*l.* 5*s.* 3*d.* *per cent. per ann.*; and this circumſtance frequently cauſes the bankers and monied perſons to employ their money in diſcounting for merchants and manufacturers, in preference to inveſting it in the public funds, particularly when the latter are at a high price. The cuſtomary diſcount, according to this method, for the time a bill has to run, is found by any table of ſimple intereſt. See INTEREST.

DISCOUNT, is alſo commonly uſed for a certain allowance which manufacturers and wholeſale dealers make on the price of their goods, either in all caſes when ſold for money or credit, or more generally, only when ſold for ready money, in lieu of a cuſtomary credit. This diſcount varies greatly in different branches of trade; thus on ſome articles it is leſs than one *per cent.*; on others, ſuch as aqua-fortis, and oil of vitriol, chariots, and coaches, cutlery, fire-arms, hoſiery, needles, plants, and ſeeds, ſadlery, &c. it is uſually five *per cent.* On black lace, fans, black lead, earthen ware, and ſome other articles, the diſcount is 10 *per cent.*, and on a few deſcriptions of goods, as ribbons, perfumery, and hardware, the uſual diſcount is ſtill greater; on ſome articles of Birmingham and Sheffield manufacture, a diſcount of 50 or 60 *per cent.* is frequently allowed.

DISCOURSE, in *Logic*, from *diſcurro*, I run over, an operation of the human mind, whereby it paſſes, or proceeds from one thing to another, that is, from a known thing to an unknown.

The ſchoolmen define it an act of cognition, whereby the mind deduces one thing from another: this it does, when, in conſequence of an aſſent given to one propoſition, it yields aſſent to another: ſo that diſcourſe conſiſts in a dependency of aſſents; and ſuppoſes ſuch an order between the acts, that that belonging to the conſequent ariſes from that belonging to the antecedent. So that the intellect is then ſaid, *diſcurrere*, to diſcourſe; when, from an aſſent to one or more propoſitions, it infers or draws an aſſent to another.

The object of diſcourſe, therefore, or that about which the intellect is employed in diſcourſing, is the connexion of extremes conſidered with regard to ſome third, or medium: thus, when it judges, that every reaſonable animal is riſible, affirming, that there is a connexion between riſibility and rationality; and then finds, there is likewiſe a connexion betwixt man and reaſonable animal; and afterwards gathering from the connexion found between riſible and man, with rational, that man and riſible have likewiſe a connexion, as both are connected with rational; it is ſaid to diſcourſe.

Hence it appears, that diſcourſe, whereon men uſe to value themſelves, does really betray the infirmity of the human underſtanding; as it denotes a chain or ſcale of ſeveral ſucceſſive acts of cognition neceſſary to arrive at a truth. So that there is no diſcourſe in God, who underſtands all things originally and truly. See REASONING.

DISCOURSE, in *Rhetoric*, is uſed in the ſame ſenſe with oration.

DISCOUS FLOWER. Botaniſts reckon two claſſes of plants with a diſcous flower. 1. Such as have the flower compounded, and the ſeed pappous, but the leaves and ſtalks not milky when broken. 2. The corymbiferous plants, whoſe flowers are compounded into a diſcous figure, but their ſeeds not pappous. Of the former kind are the fleabanes, ragweeds, groundſels, &c. and of the latter are daiſies, chamomile, tanſy, wormwood, &c. Theſe are diſtinctions founded by Mr. Ray, but not regarded by the later botaniſts.

DISCRETE, or DISJUNCT, *Proportion*, is, when the ratio between two or more pairs of numbers, or quantities, is the ſame, and yet there is not the ſame proportion between all the four numbers.

Thus, if the numbers 6 : 8 : : 3 : 4 be conſidered; the ratio between the firſt pair, 6 and 8, is the ſame as that between 3 and 4, and therefore theſe numbers are proportional: but it is only diſcretely, or disjunctly; for 6 is not to 8, as 8 to 3; that is, the proportion is broken off between 8 and 3, and is not continued all along, as it is in theſe following, which are called continual proportionals, *viz.* 3 : 6 : : 12 : 24.

DISCRETE *Quantity*, is ſuch as is not continued and joined together. Such is a number, whoſe parts, being diſtinct units, cannot be united into one continuum; for in a continuum there are no actual determinate parts before diviſion, but they are potentially infinite; wherefore it is uſually and truly ſaid, that continued quantity is diviſible *in infinitum*. See CONTINUITY.

DISCREETS, DISCRETÆ, Low Latin, certain nuns who, from their offices or their qualifications, form the council of the abbeſs, prioreſs, or vicareſs, as is ſeen in the rules and conſtitutions of the Clareſſes, Benedictines, &c.

DISCRETION, in *Law*, the faculty of diſcerning between right and wrong; and therefore whoever hath power to act at diſcretion, is bound by the rule of reaſon and law. (2 Inſt. 56. 298.) Infants, &c. under the age of diſcretion, are not puniſhable for crimes; and want of diſcretion is a good exception againſt a witneſs. (2 Hawk. 434.) See AGE, and INFANCY.

The aſſeſſment of fines on offenders committing affrays, &c. the binding of perſons to their good behaviour, and the duration of impriſonment in particular caſes, are ſubmitted to the diſcretion of all judges and juſtices of peace; and, in many caſes, for crimes not capital, the judges have a diſcretionary power to inflict corporal puniſhment on the offenders.

DISCRETIONE, in the *Italian Muſic*, is uſed to direct the ſinger or player to execute his part with care diligently.

DISCRETIVE PROPOSITIONS, are thoſe where various judgments are made, and denoted, by the particles *but*, *notwithſtanding*, or by words of the like nature, either expreſſed or underſtood. Thus, fortune may deprive me of my wealth, *but* not of my virtue; they, who croſs the ſeas, change their climate, *but* not their diſpoſition; are called diſcretive propoſitions,

DISCUS, among the *Ancients*, a name given to a round ſhield, conſecrated to the memory of ſome famous hero, and hung up in the temples of their gods, as a trophy of ſome great action.

From the figure of this diſcus, or rather of that which the Greeks and Romans uſed to divert themſelves with, eſpecially at their public games, and which was a round quoit of braſs, comes the word ſo much in uſe among aſtronomers, *viz.* the diſc of the ſun, or moon. See DISC.

DISCUS, DISCEUS, or DISCIFORMIS *Cometa*, a comet or fiery meteor reſembling a round diſh or platter. The chief of this kind is called a ſolar comet, from the likeneſs of its rays to thoſe of the ſun; it is called alſo roſa and chryſeus, from its bright ſilver colour mixed with a golden or amber one.

DISCUSSION, in matters of literature, ſignifies a clear treating or handling of any point, or problem. The word imports a ſhaking off, or diſpelling the difficulties and obſcurities with which a thing was embarraſſed. We ſay, ſuch a point was well diſcuſſed, when it was well treated of, and cleared up.

DISCUSSION is alſo uſed in a medicinal ſenſe, for a diſperſing the matter of any tumour, or ſwelling, through the pores of the body; or an evacuation of ſome thin matter gathered in any part, by inſenſible perſpiration.

DISCUSSORIA, *Diſcutientia*, διαφορητικα, *diſcutients*. See DISCUTIENTS.

DISCUTIENTS, in *Surgery*, are ſuch applications as tend to promote the abſorption of effuſed fluids or tumours, &c. All ſtimulating lotions, liniments, and even mere friction, will produce this effect; and to the ſame claſs belong Galvaniſm and Electricity. The moſt common embrocations now in uſe, as diſcutients, are ſolutions of ammonia and of ſoap, to which a proportion of alcohol is added. See TUMOUR, BRUISE, SPRAIN, and INFLAMMATION.

DISDAIN, in *Ethics*, is a high degree of contempt, or ſuch as precludes any intercourſe with the party deſpiſed.

DISDIAPASON, in *Muſic*, a compound concord, in the quadruple ratio of 4 to 1, or of 8 to 2.

The diſdiapaſon is produced when the voice goes from the firſt tone to the fifteenth, and may be called a *fifteenth*.

The voice ordinarily does not go farther than from its firſt tone to the diſdiapaſon; *i. e.* it does not go beyond the compaſs of a double octave; for the diſdiapaſon is an octave doubled. It may ſometimes riſe ſeveral tones above a diſdiapaſon, but the effort or ſtruggle diſfigures it, and makes it falſe. In reality, the ancient ſcale, or diagramma, only extended to a diſdiapaſon.

DISDIAPASON-*Diapente*, a concord in a ſextuple ratio of 1 to 6.

DISDIAPASON-*Diateſſaron*, a compound concord in the proportion of 16 to 3.

DISDIAPASON-*Ditone*, a compound conſonance in the proportion of 10 to 2.

DISDIAPASON-*Semiditone*, a compound concord in the proportion of 24 to 35.

DISEASE, in *Medicine*, that condition of the animal economy, in which one or more of the functions is altogether impeded, or is performed with difficulty or with pain.

Various definitions of diſeaſe have been given by different phyſicians Some have laconically defined it *the abſence of health*, forgetting that this involves another definition, that of *health*. Some have deſcribed it as exiſting in particular conditions of the fluids, or of the ſolids. But it is unneceſſary to enquire into the variety of definitions of diſeaſe, ſince the word is well underſtood by all, and is uſed under the ſame acceptation by the peaſant and the philoſopher.

Health and diſeaſe are relative rather than poſitive terms. Few perſons have every organ and function of the body in the moſt perfect ſtate, while yet they may be conſidered as in health; for a very conſiderable variety of condition, both in the mental and bodily functions, is compatible with health. Thus one perſon may be poſſeſſed of great muſcular ſtrength, another may be remarkable for the feebleneſs of his muſcles; yet the health in both may go on uninterrupted. One perſon may be capable of digeſting the moſt inſoluble food, and in large quantities; another may have little appetite for food, and be unable either to take or digeſt any, but the moſt moderate in quantity, or the moſt light and digeſtible in quality; yet neither ſhall be in a ſtate of diſeaſe. Thus, alſo, one ſet of individuals, reſiding in a crowded city, and another in the country, may be both healthy, *i.e.* all their functions may go on regularly, without impediment or uneaſineſs; yet the florid countenance, the ſtrong powers of muſcle, the great digeſtive faculties of the ploughman, mark a conſiderably higher health, a more perfect performance of the functions, than takes place in the inhabitant of the crowded city, whoſe complexion, ſtrength, and appetite, are obviouſly characteriſtic of leſſer powers. The terms health and diſeaſe, therefore, are in ſome degree relative, and muſt be conſidered in regard to an individual, as compared with the generality of men, and with himſelf at different times.

Diſeaſe may occur in all parts of the body, in the fluids and the ſolids, and in each particular organ and function; it may occur ſingly, in one part, or in ſeveral parts at the ſame time: hence diſeaſes may be ſimple or complicated. But the moſt ſimple diſeaſes with which we are acquainted, produce ſeveral morbid appearances, or *ſymptoms*, by which alone they are diſtinguiſhed from each other. Some of theſe are occaſional and accidental; others are conſtant, and ſerve to define and characterize the diſeaſe: and ſome again are the effects of thoſe which ariſe from the original cauſe of the diſeaſe, and are called *ſymptomata ſymptomatum*, the ſymptoms of ſymptoms.

The ſymptoms or ſigns of diſeaſes which are obſerved in the ſick, are extremely various and numerous; yet a knowledge of them is requiſite, both with a view to learn the nature of, and to alleviate or remove the diſeaſes. The ſymptoms are the external characters of diſeaſes, and by obſerving them in certain congeries or groups, like the natural hiſtorian, we acquire a knowledge of thoſe which are commonly connected, thoſe which only accidentally meet together, and thoſe which appear to be incompatible. Experience has pointed out to us the means by which certain congeries may be alleviated; and where our remedies fail, an examination of the organs, after death, enables us to obſerve the connection between certain groups of external ſigns, and the diſordered condition of certain organs. We have a ſtill more uſeful and direct guide, in aſcertaining the ſeat and nature of a diſeaſe, from its external ſigns; namely, that which ariſes out of our knowledge of the nature of the functions of each reſpective

reſpective organ in health, or from the ſcience of phyſiology; which latter is, of courſe, founded upon the knowledge of anatomy. For it muſt be obvious, that, if the function of digeſtion is impeded or ſuſpended, the ſtomach, by which that function is performed, is the organ diſeaſed; if the voluntary power, or the intellectual faculties, are impaired, the brain, which is the common centre of ſenſe and motion, is neceſſarily to be conſidered as the immediate ſeat of the diſorder. But theſe concluſions, again, frequently require the correction of obſervation and experience. For ſo great and numerous are the *ſympathies* between different and diſtant parts of the animal frame, that the functions of a particular organ are frequently diſordered when no eſſential diſeaſe exiſts in it; but when the original diſeaſe is in a diſtant organ. Thus, the ſtomach is violently diſordered, ſickneſs and vomiting being excited, when injury is done to the brain; and, *vice verſâ*, the brain is often affected with pain, giddineſs, &c. when the ſtomach is deranged. In eſtimating the ſymptoms of diſeaſe, therefore, all theſe conſiderations muſt be taken into the account.

The ſymptoms of diſeaſe in the human economy, may be uſefully referred to three heads; to impeded functions, uneaſy ſenſations, and manifeſt changes in the appearance, or other qualities of the body. For every diſeaſe conſiſts principally in the derangement of ſome function: but no function can be much impeded or deranged, without occaſioning ſome pain or uneaſineſs, by which the patient is informed of his indiſpoſition; nor can any one labour under a diſeaſe for any length of time, without ſuffering ſome change from that appearance and form of the perſon, or that complexion of the countenance, which is wont to be connected with good health, as one of its agreeable characteriſtics.

Among the ſigns of diſeaſe, thoſe of the leſions of the animal functions are particularly to be obſerved; the ſigns of derangement, for example, of the ſenſes, and the voluntary motions. Each of the external ſenſes, of hearing, ſeeing, &c. may be diſordered in various ways; they are ſometimes found dull and defective, at other times preternaturally acute, or not exerted without pain; ſometimes they are altogether deranged; the eye repreſenting objects incorrectly, or the ear confounding ſounds. The internal ſenſes, or intellectual functions, are alſo variouſly affected by diſeaſes, as in delirium, mania, melancholia, &c.; theſe demand the moſt rigid attention from the phyſician, not only becauſe theſe derangements conſtitute of themſelves diſeaſes of the utmoſt importance, but becauſe they afford ſtriking indications of the nature, increaſe, and remiſſion of other important diſeaſes, eſpecially in the various kinds of fever, inflammation, &c. Upon the ſame grounds the faculty of motion muſt be obſerved in all its leſions; whether it be ſimply defective, as occurs in diſeaſes in general, which is termed debility; or loſt, as in palſy; or preternaturally increaſed, as ſometimes happens under particular morbid ſtates of the brain; or laſtly, irregular, as in convulſions, cramp, and other ſimilar diſorders.

The ſtate of the ſick in regard to ſleep ought alſo to be attended to; for, whether we conſider it as a function of the body, or as the ſuſpenſion of other functions, it follows its natural laws, in a ſtate of health, and theſe are uſually interrupted in the generality of diſeaſes; ſo that ſleep either altogether forſakes the patient, or it is too intenſe, as in a ſtate of coma, or interrupted at ſhort intervals, or accompanied with inceſſant and frightful dreams; and it is often altogether unrefreſhing.

The conſideration of the ſigns of diſeaſe in the vital functions is of ſtill more importance, not only becauſe we hence learn more fully the nature of the diſeaſe, and the condition of the patient; but becauſe they are in themſelves dangerous, when they are ſevere. Of this ſort are all the varieties of the pulſe; the feeble, ſmall, ſtrong, hard, irregular, or intermitting pulſe, demand particular attention, as they imply a defect of the powers of the circulation and the motion of the blood, or a morbid increaſe of ſtrength and motion, or an irregular and imperfect action of the heart; theſe are eſpecially obſervable in fevers, inflammations, and faintings.

The affections of the function of reſpiration are the next in importance. The unuſual quickneſs or tardineſs of the breathing; or a difficulty, or noiſe in inſpiration, as in aſthma, the ſtertor of apoplexy, or in croup; coughing, ſneezing, ſighing, or other modifications of breathing, are all indications of diſeaſe, which muſt not be overlooked. And to theſe the various affections of the voice muſt be added.

Farther, the ſymptoms of leſion in the natural functions muſt be ſeduloufly obſerved. The hunger or thirſt, the defect, exceſs, depravation, and every unuſual condition of the appetite; the various changes in the act of eating, ſwallowing, and the errors of digeſtion, ſuch as eructations, acidity, ſickneſs, &c.; the ſtate of the bowels, whether too much bound, or too much relaxed, whether flatulent, or in pain; the condition of the ſtools, and of the other ſecretions and excretions, which come more particularly under the cognizance of our ſenſes, as the perſpiration and urine; the exceſs, defect, difficulty, or depravation of theſe reſpectively;—in a word, all the circumſtances of this nature muſt be inveſtigated. Nor are the functions peculiar to each ſex, more particularly thoſe of the female, to be overlooked.

As to the ſecond head of morbid ſymptoms, uneaſy or painful ſenſations, they are the moſt frequent concomitants and ſigns of all diſeaſes; few diſeaſes are free at leaſt from uneaſineſs. For as there is a degree of pleaſurable feeling belonging to the healthful action of all the organs of the body; ſo, when theſe are interrupted and diſturbed, the ſick man ſuffers pain, anxiety, and various diſagreeable ſenſations. Beſides the various modifications of pain which we deſcribe by comparing them with the ſenſations produced by different cauſes, ſuch as a burning, ſtinging, ſtabbing, gnawing pain, a ſhooting, throbbing, binding pain, and ſo forth; itching, tingling, a ſenſe of laſſitude, of torpor, or numbneſs, of ſtupor, of heat, of cold, of weight, naufea, giddineſs, faintneſs, ringing in the ears, and a multitude of uneaſy feelings, indicate the varieties of diſeaſe. Sometimes the ſeverity of theſe feelings conſtitutes the principal part of the diſeaſe; and they agitate and diſtreſs or terrify the patient ſo much, that they become more terrible than even the apprehenſion of death; indeed, in many caſes, theſe painful ſenſations are by no means deſtitute of danger, from whatever cauſe they originate, as they may wear out the powers of life by their inceſſant irritation.

The third head of ſigns of diſeaſe compriſes all thoſe manifeſt morbid changes, which do not come under the preceding, and which we learn from our own obſervation, and not from the words or complainings of the ſick. Theſe are the morbid colour of the body, eſpecially of the countenance, whether it be unuſually pale, red, yellow, duſky, livid, or variable; the peculiar aſpect or expreſſion of countenance, dependent on the actions of the muſcles of the face, or on the circulation of the blood, and often on the ſtate of the mind; an aſpect or expreſſion not eaſy to be deſcribed, but which affords a better index of the condition of the *vires vitæ*, and of the increaſe or diminution of diſeaſe, than any language can expreſs. In particular, the ſtate of the eyes ſhould be examined; the languor or heavineſs, unuſual redneſs, brilliancy, wildneſs, or diſtortion, and other morbid appearances of the eyes, as the hollowneſs, inequality

of

of motion, or of apparent ſize, &c. are indications of various ſtates of diſeaſe. The condition of the mouth, and particularly of the tongue, as redneſs, whiteneſs, foulneſs, blackneſs, dryneſs, afford important indications of the degree, increaſe, and decreaſe of the diſeaſe, as they remain ſtationary, or become more or leſs obvious. The peculiar odours, which ariſe from the patient, or from his excretions, ſometimes contribute to point out the nature of the diſeaſe; as the unuſual fætor of the pulmonary and cutaneous halitus; or of the whole body, as in ſmall-pox; of a part, as in cancer; the ſmell and taſte of the urine in diabetes, &c. And many of the morbid qualities of the body may be aſcertained by the touch; as the heat, cold, dryneſs or moiſture of the ſkin, which are particularly important in the febrile ſtate; and the hardneſs, rigidity, ſoftneſs, thickneſs, ſwelling, or emaciation of different parts of the body, or of the whole, in various other diſeaſes. Theſe manifeſt qualities of diſeaſe ought to be the more carefully inveſtigated; becauſe they are eaſily obſerved, and by no means fallacious, nor can they be concealed by the patients; and beſides, an obſervation of them often ſuperſedes the neceſſity of aſking many diſagreeable queſtions.

Theſe various impediments of the functions, diſtreſſing ſenſations, and obvious external changes of the body, compriſing all the morbid phenomena which are obſerved, occur under various combinations, as to number and degree, conſtituting the characters of the different diſeaſes of the human frame. Each of theſe combinations, or groups of ſymptoms, has a few permanent ones, which mark its eſſential nature. Theſe are called its diagnoſtic, or diſtinguiſhing ſymptoms, and phyſicians have long ago pointed theſe out in moſt of the forms of diſeaſe. Within a century back, theſe have been claſſed and arranged, after the manner of the natural hiſtorians, into a regular ſyſtem, each form being diſtinguiſhed by its generic and ſpecific characters. See Nosology. At preſent we treat of diſeaſe in general.

The *cauſes* of diſeaſe are conſidered by phyſicians, as three-fold; firſt, the *proximate* cauſes, which ſignify the morbid condition itſelf; ſecondly, the *remote* cauſes, which are either *prediſpoſing*, or *occaſional* cauſes, as already explained. See Cause in *Medicine*.

A pre-diſpoſing cauſe, or pre-diſpoſition to diſeaſe, is inherent in the body, although it may often originate from external circumſtances; but the occaſional, or exciting cauſe, may be either internal or external. When they concur in their influence, diſeaſe is produced, which neither could occaſion alone. For every perſon, to whom an exciting cauſe of diſeaſe is applied, does not ſuffer diſeaſe; nor do thoſe in general, who are already pre-diſpoſed to diſeaſe, fall into it, unleſs an exciting cauſe acts upon them. Some pre-diſpoſitions are obvious to our obſervation; ſuch as general or partial debility of the ſolids, a morbid irritability of the ſame parts, a fulneſs of habit, with great ſtrength, &c.; in the latter of which ſtates inflammatory diſeaſes are readily excited; in the others, nervous and chronic diſorders of various ſpecies.—There are ſome exciting cauſes of diſeaſe, nevertheleſs, ſo powerful in their agency, that however ſteady the health and ſtrength of individuals, they will produce their effects. Thus the poiſon of ſmall-pox, and of ſyphilis, will infect the ſtrongeſt; other poiſons will produce death under any circumſtances of health; and cold and heat will injure the body in various ways. And exciting cauſes, which do not immediately occaſion diſeaſe, by continuing their influence, gradually corrupt the moſt healthy conſtitution, and induce a pre-diſpoſition to various diſorders. For the ſame agent may be at one time an exciting, and at another an occaſional cauſe; as may be illuſtrated in the inclemency and viciſſitudes of the weather, in intemperance and luxury, and ſo forth. It is of conſiderable importance in the practice of medicine to aſcertain theſe remote cauſes of diſeaſes, both with a view to prevent their ill effects, and to anticipate their agency; and experience has done much in the inveſtigation, as will be ſeen under the articles of Diſeaſe reſpectively.

The remote cauſes of diſeaſes in the human body operate variouſly. Many are purely *mechanical*, and injure the mechanical ſtructure; ſuch as blows, wounds, bruiſes, ligatures, extraneous ſubſtances introduced, &c. whence originate various inflammations, impoſthumes, fractures, diſlocations, and diſeaſes in the functions of particular organs, thus injured. Others operate *chemically*, that is, decompoſe the parts to which they are applied, or interrupt new combinations of matter, neceſſary to be carried on: of the former ſpecies are ſome chemical poiſons; ſuch as cauſtic potaſs, muriate of mercury or corroſive ſublimate, nitrate of mercury, arſenic, &c.; of the latter ſpecies, is the reſpiration of gaſes or airs, not containing oxygen, or containing carbonic acid, or other deleterious ſubſtance, which interrupts the change of the blood in its paſſage through the lungs.

But the great majority of cauſes of diſeaſe act upon the living ſolid, the irritable fibre, or the nervous energy, or by what other name the animal power of being excited by ſtimulus may be denominated. This power or property is peculiar to living bodies; and various phenomena ariſe from its operation, from its exceſs or defect of exertion, from the exceſs or defect of the ſtimulation applied to it, &c. See Excitement. Perhaps the moſt common exciting cauſes of diſeaſe, through the medium of the nervous power, are *heat* and *cold*, their viciſſitudes and modifications, as with dryneſs, moiſture, &c. After Sanctorius had drawn the attention of phyſicians to the inſenſible perſpiration, and while the humoral pathology prevailed, the morbid operation of cold was ſuppoſed to conſiſt ſolely in the ſuppreſſion of the perſpiration, which was ſaid to be thrown back into the ſyſtem, and to fall upon particular organs, there producing diſeaſe. But we have no evidence of this mechanical transference of fluids; and the modern theory which attributes the operation of cold and heat to the irregularity of vaſcular action, conſequent on the great variations in the ſtimuli applied to the body, appears to be more conſiſtent with the general laws of animal economy. See Cold; Catarrh; &c. From the operation of heat and cold, which, ſtrictly ſpeaking, are but degrees of the ſtimulus of heat, inflammation is occaſionally produced in every organ of the body: hence Catarrh, Pleuriſy, Rheumatiſm, Phrenſy, &c.; hence alſo many diſeaſes of the ſtomach, the bowels, and the ſkin; and hence various idiopathic fevers in all climates.

Next to heat and cold, the influence of *food* and *drink*, as exciting cauſes of diſeaſe, acting on the nervous fibre, may be conſidered as moſt general. Theſe circumſtances, indeed, influence the body in a double manner: they tend, in many inſtances, firſt to induce a pre-diſpoſition to diſeaſes, ſo that other exciting cauſes readily act upon the conſtitution, giving riſe to various maladies: this pre-diſpoſition may conſiſt in a plethoric ſtate of the body, which is liable to inflammatory diſorders; in a debilitated ſtate, from the exceſſive abuſe of ſtrong liquors, which expoſed to various chronic complaints, &c. Or they may act both as pre-diſpoſing and exciting cauſes; thus they produce a gouty conſtitution, and this being eſtabliſhed, an occaſional debauch will bring on a paroxyſm: and the ſame may be ſaid with reſpect

to

to apoplexy and hemiplegia. In ſhort, errors in food and drink daily excite diſeaſes. Not to mention drunkenneſs and its immediate conſequences, the head, the ſtomach, the bowels, the kidnies, the conſtitution at large, are variouſly affected by this cauſe; and head-ache in all its forms; ſickneſs, acidity, flatulence, and various forms of dyſpepſia, and of thoſe diſeaſes termed bilious; colic, diarrhœa, dyſentery, and other inteſtinal affections, as well as general fever, in different ſhapes, are all the common reſult of exceſs and miſmanagement in regard to food and drink. (See DIET.) Imperfect nouriſhment, on the other hand, leads to a hoſt of chronic diſorders.

Contagions, or effluvia ariſing from the body under particular ſtates of diſeaſe, as well as the miaſmata from marſhes, &c. excite numerous diſeaſes. The mode in which they operate upon the irritable fibre is not clearly underſtood; but the laws, according to which they are propagated, have been ſatisfactorily inveſtigated. (See CONTAGION.) Their deleterious influence on the nervous ſyſtem, when in a concentrated ſtate, has in ſome inſtances been ſo great, that an almoſt immediate extinction of life has enſued. In the caſe of the plague, almoſt every nation in the world has ſuffered from the morbid effects of contagion. The ſmall-pox, ſcarlet fever, meaſles, and other ſpecific contagions, as they have been called, as well as the contagion of typhus fever, which may be produced under many circumſtances, all afford examples of this ſort of exciting cauſes of diſeaſe. Nor are the non-volatile contagions to be overlooked; the virus of ſyphilis, gonorrhœa, ſcaldhead, itch, &c. operates in a ſimilar way on the living ſyſtem, and induces a ſtate of diſeaſe reſembling that under which it was generated reſpectively.

The animal poiſons, and the vegetable narcotic drugs, have a powerful operation on the nervous power; the former chiefly when infuſed through a wound, and conveyed by the blood to the ſenſorium; the latter alſo through the medium of the ſtomach. Of the former are the poiſon of the viper, rattle-ſnake, &c.; of the latter ſpecies are opium, henbane, cicuta, belladonna, and a numerous tribe beſides; and to theſe we may add alcohol, or diſtilled ſpirits, in the various ſhapes of gin, rum, whiſky, &c. all of which have produced a multiplicity of diſeaſes, and often, when taken in ſufficient quantity, have ſpeedily annihilated the living power.

Among the cauſes of diſeaſe, acting through the medium of the nervous energy, the mental affections muſt be enumerated. All ſtrong or long continued emotions of the mind tend to produce diſeaſes; they derange all the bodily functions, eſpecially the digeſtion and the reſpiration; they interrupt the refreſhment of ſleep, and often, indeed, when ſudden and violent, at once induce diſeaſe, ſometimes death.

Errors in reſpect to ſleep and excerciſe, likewiſe often derange the nervous ſyſtem, and occaſion diſeaſes; eſpecially long watching, over-fatigue, &c.

Many diſeaſes, when once induced, become the pre-diſpoſing, and even exciting cauſes of others. The debility occaſioned by acute diſeaſes, becomes a pre-diſpoſing cauſe to the attacks of other acute and chronic diſeaſes, and eſpecially to a repetition of the ſame acute diſeaſe. Thus, a perſon who had been free from inflammatory ſore throat during the greater part of his life, being expoſed to a powerful exciting cauſe, ſuffers an attack of that diſeaſe, and henceforth the ſlighteſt expoſure to cold will bring it on again. One ſpecies of diſeaſe often excites another: thus, a tuberculated ſtate of the liver induces dropſy of the belly, by impeding the circulation through the hepatic veins, and therefore through the meſenteric and inteſtinal veſſels: ſcarlet fever often brings on anaſarca; common catarrhal inflammation of the bronchial membranes will give riſe to ulceration in the lungs, and induce a fatal conſumption, &c.

Many of the pre-diſpoſing cauſes to diſeaſes, of a particular ſort, conſiſt in obvious qualities: 1. The *age*: many diſeaſes are peculiar to infancy, others to manhood, others again to old age. Hydrocephalus, croup, the irritations of dentition, ſtrophulus, and ſome other cutaneous eruptions, occur almoſt excluſively in the early years of life: the more acute and inflammatory diſorders, as well as diabetes, conſumption, and ſome chronic complaints, are moſt frequent in the middle ages; and in the decline of life, chronic diſeaſes of the lungs, kidneys, bladder; the failure of the external ſenſes, and of the faculties of the underſtanding; palſy, chronic rheumatiſms, &c. are the prevailing diſeaſes. 2. The *ſex*. Each ſex has its peculiar prediſpoſitions in many reſpects; the male, being the more robuſt, is more liable to acute inflammatory diſeaſes; the female, poſſeſſing the more irritable fibre, ſuffers more frequently under hyſterical and nervous complaints, not to mention thoſe connected with the ſexual organs, with the ſtate of pregnancy, &c. 3. *Hereditary conſtitution*. That a liability to particular diſeaſe is tranſmitted from parent to off-ſpring, as well as a reſemblance in external form, and in manner, voice, &c. is too well known to require any evidence to be adduced here in proof of it. The ſins of the fathers are often viſited upon the children, in a phyſical ſenſe, for many generations. The gout, mania, ſcrofula, epilepſy, and many other forms of diſeaſe, are thus obſerved to deſcend through a long ſeries of deſcendants.

The exiſting cauſes of particular claſſes of diſeaſe, are likewiſe obſerved under particular circumſtances of life. Many *trades* give occaſion to certain maladies; thus the painter, the glaſs-cutter, the white-lead manufacturer, and every artiſan in the habit of uſing lead, is liable to attacks of *colica pictonum*, or painter's colic, and to a peculiar and diſtreſſing palſy of the hands, which enſues: millers, hair-dreſſers, chaff cutters, and all thoſe who are expoſed to breathe an atmoſphere, in which various ſubſtances are ſuſpended in the form of an impalpable powder, are liable to aſthma, dyſpnæa, pulmonary conſumption, and other diſeaſes of the lungs: thoſe employed in very ſedentary occupations, frequently ſuffer much from ſtomach complaints, head-ache, hypochondriaſis, and other diſeaſes of debility. Sailors, on long voyages, when confined ſtrictly to the uſe of ſalted animal food, are ſubject to the ſcurvy, a diſeaſe which is comparatively rarely ſeen, except under ſuch circumſtances. In the ſame way, armies in the field are expoſed to particular diſeaſes, dyſentery, infectious fevers, &c. (See CAMP-*diſeaſes*.) Climate, ſeaſon, and peculiar epidemic conſtitutions of the atmoſphere, are alſo ranked among the circumſtances modifying diſeaſes.

Diſeaſes have a conſiderable influence in modifying each other. We have already obſerved, that they ſometimes give riſe to one another; but they likewiſe are converted into each other; *i. e.* the original diſeaſe will excite a ſecond, and will itſelf diſappear. When a ſimilar diſeaſe is transferred from one part to another, or when a diſeaſe, of one kind, ceaſes in a part, and another diſeaſe ariſes in another part, this is termed a *metaſtaſis*. See CONVERSION *of diſeaſes*, where this point is diſcuſſed at length.

But diſeaſes alſo cure each other, or ſuſpend each other's action. It is a fact, in the animal economy, which was particularly pointed out by the late Mr. John Hunter, that certain operations of the ſyſtem are incompatible with certain others: thus, that febrile proceſs of the animal body, which produces the eruption of ſmall-pox, cannot go on at

the

the ſame time with that which brings forth the eruption of meaſles; ſo that, if the contagion of theſe two diſeaſes be received nearly at the ſame time, the one will lie dormant during the whole progreſs of the other; and that having been completed, it will then commence, and complete its own courſe independently; or if one has already begun to appear, it will ſometimes diſappear during the operation of the other contagion, and re-appear, and go through its ſtages, on the ceſſation of the latter. This is generally true with reſpect to all the febrile contagious diſeaſes, chicken-pox, ſcarlet-fever, as well as thoſe juſt mentioned. The cow-pox and the ſmall-pox continue their action together, which implies, that their operation on the ſyſtem is the ſame. The general rule, however, that no two morbid actions can take place at the ſame time, is not altogether without its exceptions. Beſides theſe contagious fevers, various other diſeaſes are occaſionally interrupted and ſuſpended by the occurrence of others; mania is ſometimes ſuſpended by fever; we have mentioned two inſtances of diabetes ſuſpended by acute diſeaſes; phthiſis pulmonalis is occaſionally ſuſpended by a ſtate of pregnancy, &c.

The *proximate* cauſes of diſeaſe are, in fact, the eſſential morbid conditions of the whole body or its parts, according as the diſeaſe is general or local; or, in other words, they imply the diſeaſe itſelf: "præſens morbum facit, ſublata tollit, mutata mutat." The ſpeculations of phyſicians, reſpecting the proximate cauſes of diſeaſe, have been very various in different ages, according to the prevalent philoſophy; a circumſtance in which their futility is implied; for the operations of nature are immutable, and theories that are founded on the obſervation of nature alone, cannot change with the caprice of ſpeculative minds. It has been the misfortune of medicine, that the ſpeculative and mechanical ſciences had received a previous cultivation; and hence, that transferring their hypotheſes upon theſe topics to the animal ſyſtem, phyſicians have diſtorted all their views of the natural operations of that ſyſtem, and therefore have deceived themſelves in what they conceive to be an inveſtigation of facts. They ſet out, in the early ages, with the doctrine of Ariſtotle, Plato, and Pythagoras, reſpecting the elements, the temperaments, the harmony of numbers, the power of uneven numbers, &c., hypotheſes, which in fact, after the lapſe of more than two thouſand years, have not loſt all their influence with mankind. As the ſciences of chemiſtry, mathematics, and mechanics, ſucceſſively claimed the attention of the philoſophers, before they had learned the neceſſity of diſcriminating between facts aſcertained by experiment and obſervation, and their own conjectures and opinions, medicine was darkened and obſtructed by the language and hypotheſes borrowed from thoſe ſciences. To the elements, qualities, concoctions, and criſes of the Greeks, commented upon at large by Galen, and adopted by the Arabians, as ſatisfactory explanations of the eſſence of all morbid conditions; the ſalt, ſulphur, and mercury, the acids and alkalies, the effervеſcences, fermentations, and ebullitions, of the chemiſts ſucceeded: next the mathematicians waged war againſt theſe doctrines, as inapplicable to the explanation of diſeaſes, and undertook to explain them by axioms, and lemmas, problems, theorems, and ſo on; with which they flouriſhed plauſibly enough on paper, but which, it ſhould ſeem, would avail them little at the ſide of the ſick. Then the doctrines of mechanical relaxation and diſtention of obſtruction, and error loci, of lentor or tenuity of the humours, &c. ſuperſeded the opinions of the mathematicians. The phyſicians of the laſt century have gradually approached to a more accurate knowledge of the cauſes of diſeaſe, by the cultivation of anatomy, and phyſiology, by a more cloſe and experimental inveſtigation of the phenomena of health and diſeaſe: and that principle in the animal body, the nervous power, or irritability, which was firſt attended to in the ſchools of Hoffman and Stahl, has gradually been appreciated, and acknowledged, as the peculiar characteriſtic of the living body, in the ſyſtems of Cullen, Brown, and Darwin, and in the writings of practical phyſicians. Thoſe phyſicians, it is true, more eſpecially the two latter, have too haſtily generalized the facts, which have been aſcertained on this ſubject, and therefore their hypotheſes are ſharing the fate of thoſe of their predeceſſors. See MEDICINE. This is the age of experiment in medicine, rather than of ſyſtem and hypotheſis; but much remains yet to be done, before we can attempt to give a ſatisfactory account of the proximate cauſes of diſeaſes in general. Many morbid changes take place, which are not accompanied by any palpable or viſible alterations in the ſtructure of parts, but are cognizable by the derangements of the functions only; ſuch are the extreme depreſſion of muſcular ſtrength in the onſet of fever; the morbid increaſe of it in ſome forms of mania; &c. which depend upon ſome condition of the nervous power, which can only be appreciated by the obvious phenomena that are connected with it.

It is with theſe phenomena or ſymptoms alone, therefore, that the phyſician is required to occupy his attention; and, by means of theſe external ſigns, he will be able to diſcover thoſe varieties of the internal condition of the body, which will guide him ſafely and uſefully in the application of his remedies; although he may be unable to ſtate the eſſence of diſeaſes, as the natural philoſopher is unable to explain the eſſential nature of gravitation, electricity, or magnetiſm, but nevertheleſs ſatisfactorily traces their laws. An obſervation of the different morbid phenomena, as they are combined in different forms of diſeaſe, conſtitutes what is technically termed, the DIAGNOSIS, and is neceſſarily implied in every rational attempt to cure diſeaſes.

One of the moſt obvious and general diſtinctions which occurs to the obſerver of diſeaſes, is that of the two great claſſes of *acute* and *chronic* diſeaſe. *Acute* diſeaſes are thoſe, in which there is a great and ſudden perturbation of the vital and natural functions; as frequent pulſe, thirſt, quick reſpiration, heat of ſkin, and the other phenomena of fever; the animal functions alſo frequently ſuffering as in delirium, phrenſy, &c. They neceſſarily run through their courſe, and terminate in death, in recovery, or in ſome chronic diſeaſe, within a ſhort ſpace of time. The various continued, remittent, and exanthematous fevers, as well as the organic inflammations, cynanche, pleuriſy, enteritis, &c. are examples of acute diſeaſes. *Chronic* diſeaſes, from χρόνος, *time*, are ſuch as, on the contrary, produce ſlow and gradual changes in the health; they are not attended with any violent and continued perturbations of the functions, and may go on for months, and even years. They are not connected with fever, properly ſo called, but are often accompanied by the daily paroxyſms of *hectic* fever; which, without violently diſturbing the functions, contributes, by the daily repetition of its irritations, to wear out the vital powers. Phthiſis pulmonalis, tabes meſenterica, and other forms of decline, dropſies, ſcurvy, diabetes, &c. are examples of chronic diſeaſes.

Another diſtinction of diſeaſes, is of thoſe which are *general*, or affect the functions of the body in general, and thoſe which are *local*, or are confined in their effects to ſome particular part. Perhaps it is not ſtrictly correct to ſpeak of a general diſeaſe; if there is a diſeaſe in which the whole ſyſtem is affected at once, it is idiopathic fever; but even in this complaint, it is diſputed whether there be not, as in all other

other inſtances, ſome local diſorder, which excites the morbid action in the ſyſtem at large, by a general ſympathy. See Clutterbuck's Eſſay on Fevers, 1807. For practical purpoſes, however, it is proper to diſtinguiſh thoſe morbid appearances, which are connected with ſome conſtitutional diſorder, from thoſe which are merely local; becauſe the remedies of the firſt muſt be applied through the medium of the conſtitution at large, by the ſtomach, the cutaneous abſorbents, &c. to the diſeaſed parts; while thoſe of the laſt muſt be applied immediately to the parts themſelves. Thus the local cutaneous eruptions, in ſyphilis, require the ſtate of conſtitution to be thoroughly changed by medicine, before they can be cured; thoſe of itch, ring-worm, &c. can be removed only by external topical applications; and conſtitutional remedies are of no avail.

For the other diſtinctions of diſeaſe, ſuch as corporeal and mental, inflammatory, ſpaſmodic, &c. ſee NOSOLOGY, INFLAMMATION, &c.: and for the diagnoſtics of the particular denominations of diſeaſe, ſee the generic titles reſpectively.

There is another diſtinction, which it may, perhaps, appear to be unneceſſary to notice, namely, that of *feigned* diſeaſes, from thoſe which are *real*. But deceptions of this kind are conſtantly practiſed, from various motives, both upon medical practitioners and upon the world at large; in public hoſpitals, and other charitable inſtitutions, impoſitions of this ſort are but too commonly attempted. The only means of diſcrimination are to be found in the incongruity of the deſcriptions, or of the ſymptoms which the patient exhibits, with the appearances obſerved by the practitioner. Thus, if the functions of the ſtomach go on well, if the ſleep is good, if the pulſe is calm, and the tongue without fur, it would be obvious in general that no very acute ſymptoms could exiſt, whatever might be the pretended account of the patient's feelings. Under ſuſpicious circumſtances of this nature; in the Royal Infirmary at Edinburgh, Dr. Cullen uſed to inflict the puniſhment of a bliſter, intimating to the ſtudents that his object was to detect a deception. "Applicetur emplaſtrum veſicatorium," he would ſay, "ad eliciendam veritatem;" to draw out *the truth*. Nervous diſeaſes, particularly hyſterical and convulſive fits, are doubtleſs often feigned, for ſiniſter purpoſes: catalepſy, as authors have deſcribed it, was believed by Dr. Cullen to be always a feigned diſeaſe. A curious volume might be formed of the hiſtories of deceptions of this kind; and of the diſeaſes actually inflicted by individuals upon themſelves, for which they have applied for medical aid, in hoſpitals, &c. and continued to keep up the diſorders, to the great perplexity of their phyſicians, till their deceptions were detected by accident. One woman was actually expoſed on the table before the ſtudents of a large hoſpital in London, preparatory to the operation of lithotomy; but by the caution of the ſurgeon the extraordinary deception was detected; a hard ſubſtance being diſcovered to have been artificially introduced into the vagina.

Numerous and various, however, as are the real diſorders, to which the human conſtitution is expoſed, it is not deſtitute of hope, or of the means of a reſtoration of health, when diſeaſe has once invaded it. For it is happily poſſeſſed of an internal power, which preſerves it from the ill effects of many diſeaſes, and which ſpeedily diſſolves ſome, already begun, and carries others through their courſe more ſlowly to convaleſcence. This power of the animal economy has been denominated the *vis medicatrix naturæ*, and in the theories of ſome phyſicians has been conſidered too much in the light of a rational agent. The term, in fact, merely implies a diſpoſition in the conſtitution to recover from its diſeaſes: and it muſt be obvious, that, if ſuch a diſpoſition did not exiſt, it would be vain to attempt to cure them by medicine. For all that medicine, of the moſt active powers, can effect, is to excite, to direct, and to regulate that diſpoſition. Medicine has no influence on the dead body; and, uſed contrary to the natural efforts of the conſtitution, is of no avail. By the force of this diſpoſition wounds heal, hæmorrhages are ſuppreſſed, fractured bones re-unite; and many noxious matters are ejected from the body, by the very morbid actions which themſelves excite; and thus many evils, which were otherwiſe beyond the reach of art, diſappear ſpontaneouſly, without any external aſſiſtance. It is, therefore, of the higheſt importance to obſerve minutely the powers of the conſtitution, and the tendency of their operation; that, in the cure of diſeaſes, we may ſtimulate them, when too languid, or, when obviouſly deficient, we may imitate their actions by art. Much of the recent improvements in the medical art conſiſts in having exploded many of the abſurd interferences with the proceſſes of nature in the conſtitution; and in many diſeaſes, eſpecially of the febrile kind, when no organ of the body is particularly ſuffering, the principal buſineſs of the phyſician is to watch the progreſs of the natural efforts, to prevent all unneceſſary interference, and to be active only when the vital organs are likely to ſuffer.

The actions of the conſtitution, however, are not always to be confided in as ſalutary; ſometimes they are too weak to be uſeful; at other times they are vehement, and exceſſive, inſomuch that more miſchief is to be apprehended from their continuance, than from the diſeaſe itſelf. In ſlight diſorders the conſtitutional efforts are ſufficient to reſtore the health: but no phyſician could ſafely truſt the lues venerea, or inflammations of the viſcera, to the *vires medicatrices naturæ*; for in the former, no ſalutary effort whatever is made by the conſtitution; in the latter, the vehemence of its efforts is pregnant with danger, as they tend the more certainly to gangrene, or to ſuppuration, which, in the internal organs, is ſcarcely leſs fatal.

It is neceſſary, therefore, to be on our guard againſt a double error; and neither to neglect the efforts of nature too much, on the one hand, nor to bend to them too religiouſly on the other. For it is, obviouſly, ſo far from being always expedient to follow her footſteps cloſely, that it is often requiſite to purſue a contrary march, and to oppoſe the exertions of the conſtitution by all poſſible meaſures. Indeed in the profuſion of ſubſtances in exiſtence, which have extenſive powers over the human economy, and produce various and moſt ſtriking changes in its condition, nature appears to ſuggeſt to man this occaſional interference with his conſtitution. Thus many cauſes of diſeaſe may be converted, by the ſagacity of the phyſician, into the moſt uſeful auxiliaries in his art; ſince whatever violently ſtimulates the animal frame, may be, under one mode of adminiſtration, the cauſe of death, and, under another, the beſt remedy. Such are, in fact, the powers of the moſt valuable medicines, as opium, mercury, the mineral acids, &c.

Experience, then, guided by a knowledge of the cauſes and tendencies of diſeaſe, muſt teach us when to look on as quiet ſpectators, when to aid, and when to reſtrain the morbid efforts of the conſtitution. The phyſician, therefore, who with this knowledge and experience combines an acquaintance with the properties and effects of medicines, will ſeldom be perplexed in determining upon effectual meaſures of relief, againſt the various diſeaſes that may occur. The mode of fulfilling his views, in the uſe and choice of remedies, conſtitutes the art of THERAPEUTICS; which ſee.

Many writers of underſtanding have affected to deſpiſe the art of curing diſeaſes, conſidering it as built entirely upon

upon conjecture, unſupported by thoſe inductions from well aſcertained facts, on which the phyſical ſciences reſt; and conſequently as guided by no better rules than thoſe which the caprice or ſhrewd gueſſes of individuals may have ſuggeſted. And ſome phyſicians, it muſt be acknowledged, have given cauſe for ſuch opinions, in all ages, by the abſurdity of their hypotheſes; while others, by the ſolemn myſtery with which they have attempted to cloak their ignorance, or to give an air of importance to the profeſſion, have excited a ſuſpicion that concealment was neceſſary for the ſucceſs of a craft, which would be contemned for its imbecility, if expoſed. But this myſtery is deprecated by all rational phyſicians. The truth is, that the phenomena of the animal economy are as regular and immutable as the other phenomena of nature; and conſequently are as open to obſervation, and as capable of generalization and arrangement; that is, of being reduced to a ſcience, as the other departments of natural knowledge. The facts, indeed, have not as yet been ſufficiently noted, to enable us to form a perfect theory; as is likewiſe the caſe with the chemical, electrical, and magnetical ſciences. Much yet remains to be done, but much alſo has been done, in all thoſe ſciences, and in medicine, among the reſt, in the courſe of the paſt century. The ſyſtem of abſorbent veſſels, of ſo much importance in the animal economy, has been diſcovered; a nearer approximation to the knowledge of the proceſs of reſpiration, and the changes of the blood in its courſe, has been made by the aid of chemiſtry; the phenomena of irritability have been the ſubject of ſucceſsful examination, to a great extent, and many of its laws aſcertained, both in health and diſeaſe; the effects of many powerful agents on the animal body have been diſcovered experimentally, and many general concluſions reſpecting them obtained, ſuch as thoſe of cold, of heat, of contagion, and ſome active remedies, arſenic, mercury, &c. have been more amply appreciated, within the period juſt mentioned. The ſcience of medicine, therefore, like other branches of natural knowledge, is in a courſe of advancement, and that upon the ſame ſure grounds of obſervation and experience. The hiſtory of diſeaſes will alſo afford ample evidence of the progreſs of this improvement. The contagious diſeaſes of the old world are greatly diminiſhed in their extent and fatality. Of the plague we know little more than hiſtory teaches us: the ſcarlet fever, which, under a hundred denominations, was the ſcourge of Europe for ſeveral centuries, is now comparatively rendered harmleſs. (See Willan on Cutan. Diſeaſes, part iii.) The ſmall-pox has been ameliorated by inoculation and cool treatment, and now appears likely to be exterminated by the diſcovery of the cow-pox. And many other individual diſeaſes may be enumerated, of which the fatality has been greatly diminiſhed.

In ſhort, as facts accumulate, the ſcience advances towards certainty and perfection. The circumſtances which influence diſeaſe in the animal economy are numerous; their combinations, perhaps, innumerable; ſo that the ſcience of life is neceſſarily more complicated than that of dead matter; but the principles on which they both are founded are the ſame, *viz.* fact aſcertained by experiment. The variety and complication of the phenomena of health and diſeaſe point out, in the moſt irrefragable manner, the neceſſity of various applications, in the way of remedy, and the conſequent abſurdity of the expectation that any one remedy can be effectual in the cure of all, or of many diſeaſes. Nothing, therefore, except the effrontery of empirics, can equal their error and falſehood, in the aſſurances of the general virtues of the remedies which they promulgate.

The power of the mind over the diſeaſes of the body is very conſiderable; inſomuch that very ſtrong impreſſions, excited in the former, will often remove the diſorders of the latter; eſpecially impreſſions of hope and confidence. This power was ſtrongly illuſtrated in the influence of the profeſſors of animal magnetiſm, and more lately in the uſe of the tractors of Perkins in the cure of many ſlight diſeaſes. There can be little doubt that this principle influences the effect of remedies, under the beſt adminiſtration, and aids their curative operation. (See Dr. Haygarth's pamphlet on the influence of imagination in the cure of Diſeaſes. See alſo Dr. Franklin's report of the French commiſſioners, appointed to inveſtigate animal magnetiſm.) Hence, there can be little doubt, that many remedies have obtained the reputation of efficacy in the cure of diſeaſes, which, in conſequence of the confidence of the patient in their virtues, or ſome other impreſſion on the mind, have been followed by a recovery of health, in the procuring of which they had phyſically no influence.

The reader will find the indications of cure, and the remedies, which experience has ſuggeſted for the fulfilment of thoſe indications in the various forms of diſeaſe, under the titles of thoſe diſeaſes reſpectively. See Gregory Conſpect. Med. Theoret. tom. i.

Diseases *of Plants*, in *Vegetation*, are ſuch affections as take place in vegetables from ſome derangement in the actions or functions either of the whole, or ſome particular part of them. They proceed from a great variety of different cauſes, and have very different appearances as they affect the wood, the bark, or the leaves of the plants. Theſe diſeaſes may, perhaps, be conſidered, in moſt caſes, as proceeding from internal decay, a morbid ſtate of the circulating fluids, blights, lightning, and the attacks of animals of the inſect kind.

But as particular trees and plants are liable to be affected by particular diſeaſes, their cauſes, nature, and means of removal, will be more properly treated of under the names by which they are uſually denominated, and after deſcribing the plants. See Plants, *diſeaſes of*.

DISEL, in *Geography*, a town of Perſia, in the province of Khoraſan; 18 miles S. E. of Herat.

DISEMBARK, ſignifies to land goods from on ſhipboard.

DISEMBODY. See Embody.

DISEMBOGUE. When a ſhip paſſes out of the mouth of ſome great gulf or bay, they call it diſemboguing. They ſay, alſo, of a river, that at ſuch a place, or after it has run ſo many leagues, it diſembogues itſelf into the ſea.

DISENTIS, or Dissentis, in *Geography*, a ſmall town of Switzerland, in the canton of the Griſons, ſituated in a mountainous but fertile diſtrict, irrigated by two ſources of the Rhine, and remarkable for a rich abbey, which is ſaid to have been founded in the ſeventh century, and of which St. Sigiſbertus is reported to have been the firſt abbot from the year 1614 to 1636. It is ſituated between Tavetſch and Trons. The abbot of Diſentis, Peter of Pictlingen, was one of the three patriots who firſt ſwore allegiance to the Helvetic confederacy under the lime tree at Trons.

DISERGOT, in the *Manege*. See Ergot.

DISFIGURING, in *Law*. See Mayhem.

DISFRANCHISING, the taking away one's freedom, or privilege. See Franchise.

DISGORGE, in the *Manege*, is uſed for diſcuſſing or diſperſing an inflammation or ſwelling: thus, if a horſe's legs are gorged or ſwelled, we ſay he muſt be walked out to diſgorge them.

DISGRACE, in a *Military Senſe*, has various modifications; from abſolute infamy to ſimple reprimand; it is alſo variable in its extent according to the rank of the perſon to whom

whom reprehenſion may be given; thus, what would be but a ſlight reprimand to a young officer, would, if uſed towards a veteran, who ſhould be ſuppoſed to underſtand the whole of his duty, and to act on all occaſions with the ſtricteſt propriety, be a ſevere cenſure, and tend to degrade him in the minds of his equals. The term diſgrace is, however, generally applied to the puniſhment inflicted by a court martial; eſpecially when the ſentence is to be carried into effect upon an officer in a public manner; ſuch as reading the deciſion of the court on a parade in front of a body of troops; though it is more uſual to diſpenſe with the attendance of the party, unleſs in caſes of cowardice, and ſuch ignoble conduct as demands the moſt exemplary puniſhment. The policy of debaſing the ſubordinates from witneſſing the expulſion of an officer is certainly proper; hence we conſider the ordinary mode of deputing a perſon to deliver the ſentence to the offender, to be highly politic and commendable.

But where the court have reſolved to break an officer in the moſt ſevere manner, which is always implied under the terms of "breaking with infamy," the foregoing diſpenſation cannot with propriety be indulged in. The party, on ſuch occaſions, muſt be brought to the parade; when the ſentence having been publicly announced, and his majeſty's approval declared, the officer, who is immediately inſtrumental in carrying the ſentence into execution, breaks the culprit's ſword over his head, and after cutting his ſaſh into pieces, tramples them under foot, and conducts the party beyond the limits of the camp or garriſon. In ſome ſervices the ceremony is performed under a gibbet, but more eſpecially when the court have ſentenced the offender to death, and that the ſovereign commutes the puniſhment to breaking with infamy.

It, however, is to be obſerved, that no officer, or ſoldier, can be broke *with infamy* except by the deciſion of a competent court; and the impoſing ſuch a puniſhment upon any man, in lieu of any other, even of death, is obviouſly againſt the ſtatute, becauſe a perſon broke with infamy is incompetent to become a witneſs in any cauſe; whereas one convicted of any crime whatever, provided he obtain the king's pardon, is reſtored to his credit, and may be adduced as a teſtimony in any court, civil or military; at leaſt ſuch are the opinions of our beſt law authorities, ſuch as Hawkins, Holt, and Hale, who all admitted a pardoned felon to give evidence, while they invariably rejected ſuch as had ſtood in the pillory, or had been publicly whipped, or who had been branded by the ſentence of any court having juriſdiction competent to inflict ſuch puniſhments.

It therefore behoves every perſon in authority, eſpecially military men, who are not always ſufficient judges of the law, to be very careful how they commute puniſhments; at leaſt without conſent of the party; but even that might not ſave them from damages in a civil court, ſince the fear of death, &c. might be urged in plea for an aſſent, and be found a ſufficient ground for proſecution.

Diſgracing a regiment is, eraſing its number from the military calendar: this has on various occaſions been done, the corps being firſt broken and its colours burnt.

A ſoldier is held to be *in diſgrace*, who is obliged, for any ſpecified number of days, to wear his coat the wrong ſide outwards, ſo as to diſtinguiſh him from the deſerving part of the regiment. We regret much that ſuch means are not more generally reſorted to, for the puniſhment of ſlight offences: from what we can collect, many very important reformations have been effected by attacking the pride, rather *than the backs of the ſoldiery*.

DISGUISE. Perſons doing unlawful acts in diſguiſe, are, by our ſtatutes, ſometimes ſubjected to great penalties, and even declared felons. Thus, perſons convicted of hunting in diſguiſe, in foreſts, parks, or warrens, or of unlawful hunting in the night, are to ſuffer as felons. But the principal act of parliament, in this reſpect, is that commonly called the *Black Act*, which ſee.

DISH, in *Mining*, is a trough made of wood, about twenty-eight inches long, four inches deep, and ſix inches wide; by which all miners meaſure their ore. If any be taken ſelling their ore, not firſt meaſuring it by the barmaſter's diſh, and paying the king's duties, the ſeller forfeits his ore, and the buyer forfeits, for every ſuch offence, forty ſhillings to the lord of the field, or farmer. See MINING.

DISHERISON, an old word of the ſame import as diſinheriting. Our lord the king, conſidering his own damage, and diſheriſon of the crown, &c. Stat. 20 Ed. I. 8 Richard II.

DISHERITOR, a perſon who diſherits, or puts another out of his inheritance. The ſheriff ſhall, forthwith, be puniſhed as a diſheritor of our lord the king, and his crown. Stat. 3 Edw. 1. c. 39.

DISHNE, in *Geography*, a town of Egypt; 16 miles N.E. of Menuf.

DISIMIEU, a ſmall town of France, in the department of the Iſerè; 3 miles S.E. of Cremieu.

DISINTEGRATION, in *Geology*, implies the ſeparation of the integrant parts of mountains and ſtrata, by the viciſſitudes of the atmoſphere, the abſorption and congelation of water in conſequence of the ſudden dilatations and contractions thereby produced, &c.; by means of diſintegration, the primitive mountains are ſuppoſed by ſome to have been ſo far lowered, degraded, and decompoſed, as to have furniſhed matter for the ſubſequent formation of what they call the ſecondary ſtrata: this opinion ſeems, however, to be faſt giving way, and the DEPOSITION *of Strata*, (ſee that article) to be accounted for, on principles ſimilar to thoſe which operated in the formation of the ſubſtances called primitive.

DISJUNCT PROPORTION. See DISCRETE *Proportion*.

DISJUNCTIVE denotes ſomething that ſeparates or disjoins. Thus, disjunctive conjunctions ſignify a ſpecies of words which bear this contradictory name, becauſe, while they disjoin the ſenſe, they conjoin the ſentences; or, whilſt they connect a diſcourſe, they ſeparate its parts; or, they are ſuch as denote the relations of diverſity, or oppoſition. Of theſe disjunctives, ſome are ſimple, and ſome adverſative; for an account of which, ſee ADVERSATIVE and CONJUNCTION.

DISJUNCTIVE *Propoſitions*, in *Logic*, are compound propoſitions, conſiſting of two members, or parts, connected by a disjunctive conjunction.

The firſt propoſition of a dilemma is uſually a disjunctive propoſition.

> "You muſt either obey the king, or be a rebel.
> But you muſt not be a rebel.
> Therefore you muſt obey the king."

DISK. See DISC and DISCUS.

DISK, in *Botany*, the central part of a compound, or ſyngeneſious flower, oppoſed to the marginal, or radiant part. The diſk is either flat, as in the Ox-eye, or *Chryſanthemum*, or conical, as in the Daiſy. Its colour is almoſt univerſally yellow; ſometimes white, as in *Achillea*, in which caſe, the radius alſo is white, or reddiſh. "No inſtance is known of yellow rays with a white, red, or blue diſk." Sm. Introd. to Botany, 308.

Diſk is alſo uſed for the middle part of the upper ſurface of a leaf, excluſive of all lobes, ſegments, or indentations.

DISKO Bay, in *Geography*, a large bay of Greenland, ſeparating the main land from the iſland of Diſko; in which bay there is a multitude of ſmall iſlands, the principal being the Weſt, Whale, Green, Dog, and Dunk iſlands. Some of theſe are extended eaſtwards as far as Spiring bay, and ſome northwards to Diſko iſland. N. lat. 68°—70°. W. long. about 45° 46′. The whole bay is about 160 leagues in circumference. The land is high, flat above, and covered with ice. Beneath, near the ſhips' road, the country is flat and level. The Dutch maps intimate, that on a place they call Schaus, good coals have been found, but they were never uſed. On this iſland are many rein-deer, which are found on no other iſland. The water between this and the firm land is called Waigat, and is ſix leagues broad. The fiſhery in the bay is the beſt in the whole country; in the winter, when the water of the bay is frozen, the Greenlanders take a multitude of ſeals on the ice, and in the ſpring they catch ſmall whales, and ſometimes large ones. Many Dutch whale fiſhers have formerly been accuſtomed to viſit this place every year. Diſko bay is the moſt populous place on the coaſt, except thoſe parts fartheſt to the ſouth, where no colonies have been eſtabliſhed. Diſko is alſo the beſt place for trade. Several colonies were eſtabliſhed by the Moravian miſſionaries, in the vicinity of this bay, from the year 1734, to the year 1758. The Greenlanders of Diſko ſay, that the country is inhabited for 209 leagues upward, that is, as far as the 78th degree, but very thinly; for though there is plenty of eider-fowls, white bears, ſeals, and whales, yet no perſon wiſhed to live there for a long time, on account of the tedious melancholy winter nights. They alſo were in want of food and iron, which they procured in barter from the Southlanders for unicorn-horn. The land was nothing but dreary rock and ice, and did not produce ſo much graſs as they uſed in their ſhoes, and, therefore, they were under a neceſſity of bartering alſo for graſs. Inſtead of making their houſes with wood-work and turf, they make them with the horn of unicorn-fiſh, clay, and ſeal-ſkins. The land is ſaid to ſtretch N.W., towards America, and is fenced with many iſlands. Here and there, it is ſaid, there are ſtones ſtanding erect, with arms extended, like the guide-poſts in our country. Fear has ſuggeſted to the inhabitants, that there ſtands a great "Kablunak," or European, on a certain hill, to whom they offer a piece of whale-bone when they paſs by. A miſſionary reports, that in Diſko bay, on a point which the whale-fiſhers ſay is 300 fathom deep, ſeveral ice mountains have ſtood faſt for many years; one of which they call the city of Harlem, and another, Amſterdam. Sometimes they faſten their ſhips to them, and unload their train-barrels on the flat ice. Crantz's Hiſt. of Greenland, vol. i.

DISLOCATION, in *Geology*, ſignifies the diſplacements of the parts of mountains, and the pieces of the ſtrata of the earth, from the ſituation which the ſame once occupied, when in contact with each other. The fiſſures, faults, flips, dykes, troubles, hitches, traps, rifts, breaks, loads, veins, knots, &c. which occaſion theſe diſlocations, are evident fractures of the matters compoſing the cruſt of the earth, after the ſame had aſſumed a ſolid form, and their edges, in moſt inſtances, preſent evidence of the moſt violent mechanical action, and rubbing againſt each other (Philoſophical Magazine, xxviii. p. 120.) indicating their having frequently ſlid, or ground againſt each other, even where no alteration in the level of the diſlocated parts of the ſtrata are now obſervable. See Continent, Denudation, &c.

DISLOCATION, in *Surgery*. See Luxation.

DISMAL, in *Geography*, a ſwamp of N. America, in the townſhip of Milton, Lincoln county, Maine.

Dismal *Swamp*, called the "Great Diſmal," in order to diſtinguiſh it from another ſwamp called Diſmal in Currituck county, is a very large bog, extending from N. to S. near 30 miles, and from E. to W. at a medium, about 10 miles; partly in Virginia, and partly in N. Carolina. Five navigable rivers, beſides creeks, riſe from it; two run into Virginia, *viz.* the S. branch of Elizabeth, and S. branch of Nanſemond river; and three into N. Carolina, *viz.* North river, North-weſt river, and Perquimons. The heads of theſe rivers lie concealed in the Diſmal, as no ſigns of them appear above ground, and therefore the ſwamp from which they originate muſt be amply ſupplied either from ſubterraneous ſtores, or by the water that drains into it from the high lands. The ſkirts of the ſwamp towards the N.E. are overgrown with reeds, 10 or 12 feet high, interſperſed every where with bamboo briars. Among theſe grows here and there a cypreſs, or a white cedar. Towards the S. end is a large tract of reeds, which being conſtantly green and waving in the wind, is called the green ſea. In many parts, eſpecially on the borders, is found, in abundance, an ever-green ſhrub, called the gall-buſh, from its bearing a berry, which dyes a black colour like the gall of an oak. No beaſt, bird, reptile, or inſect, approaches this horrible deſert. The noxious vapours that aſcend from it infect the air about it, and occaſion agues and other diſtempers to the neighbouring inhabitants. This dreadful ſwamp was judged impaſſable, till the line, dividing Virginia from N. Carolina, was carried through it, in N. lat. 36° 28′, in the year 1728, by order of king George II.; the men employed were not without apprehenſions of being ſtarved, as they were ten days in accompliſhing the work. This ſwamp is chiefly owned by two companies, *viz.* the Virginia company, of which Gen. Waſhington was one, owning 100,000 acres, and the N. Carolina company, which owns 40,000 acres. In the midſt of the ſwamp is a lake, about ſeven miles long, called "Drummond's pond," whoſe waters diſcharge themſelves into Paſquotank river, that empties into Albemarle ſound, and on the north into Elizabeth and Nanſemond rivers, which fall into James river. A navigable canal is forming in order to connect the navigable water of Paſquotank and Elizabeth river, through a diſtance of about 14 miles. This canal will open an inland navigation from the head of Cheſapeak bay, including all the rivers in Virginia, to George-town in S. Carolina; and when the ſhort canal from Elk river to Chriſtiana creek is opened, the communication will extend to Philadelphia and the other parts connected with Delaware river. Morſe.

DISMASTED, in *Sea Language*, denotes the ſtate of a ſhip, when ſhe has loſt her maſts by engagement or bad weather.

DISMEMBERED, in *Heraldry*, is applied to birds that have neither feet nor legs; as alſo to lions and other animals, whoſe members are ſeparated. See Membered.

DISMES, *Decimæ*, in our *Law Books*, tithes. See Tithe.

DISMISS, in a *Military Senſe*, relates to the diſcharge of an officer from the king's ſervice. This is occaſionally rendered highly diſgraceful, as well as injurious in a pecuniary ſenſe, by a prohibition againſt the party being re-admitted to any military ſituation; in ſuch caſe the ſentence ordinarily runs, "to be diſmiſſed and rendered incapable of ſerving his majeſty in any *military* capacity." This diſtinction has been rendered highly neceſſary, on account of the circumſtances which attended the late lord George Sackville, whoſe admiſſion into the houſe of peers, and eſpecially into his majeſty's privy council, was ſtrongly oppoſed, be-

cauſe

cauſe he had been diſmiſſed by a court martial, which adjudged him to be diſqualified from being again employed by his majeſty. It requires but little conſideration to decide the foregoing queſtion; the ſenſe of the court was obviouſly founded on his lordſhip's conduct as a ſoldier; and could neither diſqualify him as a counſellor, nor as a peer. Beſides, his reſtoration to the king's favour, was, in itſelf, tantamount to a pardon.

DISMISS, is alſo a word of command occaſionally given to troops on a parade, when it is intended they ſhould retire to their barracks, &c.

DISMISSION *of a bill*, in *Chancery*. If the plaintiff does not attend on the day fixed for the hearing, his bill is diſmiſſed with coſts. It may alſo be diſmiſſed for want of proſecution, which is in the nature of a NON-SUIT at law, if he ſuffers three terms to elapſe without moving forward in the cauſe.

DISMOUNTING, in the *Military Art*, the act of unhorſing. Thus, to diſmount the cavalry, the dragoons, or the like, is to make them alight.

To DISMOUNT *the cannon*, is to break their carriages, wheels, and axle-trees, ſo as to render them unfit for ſervice.

Horſes are alſo diſmounted when they are rendered unfit for ſervice.

DISNEY, JOHN, in *Biography*, was born at Lincoln in the year 1677. At the grammar ſchool in that city he received the early part of his education, and afterwards ſtudied at a private academy among the Diſſenters, to whom his father was attached. He was next entered at the Middle Temple with a view of making himſelf ſo far acquainted with the law as to enable him to become reſpectable as a magiſtrate and an author. The former character he ſuſtained with dignity and much reputation: he was diligent, diſintereſted, and impartial in his deciſions: he took an active part with thoſe who formed themſelves into a ſociety for the ſuppreſſion of vice and immorality. His regard to duty gained him the reſpect of the wiſe and good, and on ſome occaſions he was ſingled out as meriting the thanks of the judges of the circuit for ſervices that he had rendered his country. As he advanced in life, and after he had acted as a magiſtrate more than 20 years, he conceived the deſign of becoming a miniſter in the church of England, with which he had communicated from the time that he had attained to manhood. He was firſt ordained a deacon, and afterwards in 1719 a prieſt. In the ſame year he was preſented with the vicarage of Croft, and to the rectory of Kirby-ſuper-Baine, both in his native county. In the year 1722, he was inſtituted to the vicarage of St. Mary in Nottingham, to which town he removed; and here he remained till his death in the year 1729-30. As a clergyman he was remarkably attentive to the duties of his profeſſion, and his own conduct was in complete uniſon with the precepts which he delivered as the rule of life: he was admired as a preacher; reſpected and beloved as a man. He publiſhed many works; and left behind him ſtill more in MS.; of theſe we have a full account in the Biographia Britannica, to which our readers muſt be referred for more particulars relating to this excellent man. Biog. Brit.

DISŃIA, or DISSIMA, in *Geography*, an iſland or peninſula of Japan, on a rock of which the Dutch had formerly their factory, and from which they carried on a conſiderable trade.

It is ſeparated from the city of Nanguazak only by a river and a wall, which divides the traders from all communication with the town. The iſland is about two miles in compaſs; and no Dutchman was allowed to ſtir out of it, during the whole time of his ſtay, or about nine months in the year, without danger of being cut to pieces by the guards, which were ſet over them, and guarded the bridge over the river that parted them from the city. They were not permitted to converſe either with the guards, or with any natives, except ſuch as were appointed by the governor as factors, brokers, or to ſome other ſuch office. They were not ſuffered to have a lighted candle in their houſes, any more than on ſhip board; and if the centinels heard any uncommon noiſe, or perceived any diſturbance among them, they gave immediate notice of it by blowing a horn; upon which a party was diſpatched by the governor, with an officer at their head, to inquire into the occaſion of it, and either puniſh, or, at leaſt, ſeverely threaten the offenders. During the ſix weeks of open trade, great numbers of Japaneſe came into the iſland, and put up their rich booths, furniſhed with all manner of merchandize. They amuſed themſelves with gaming, drinking, and converſing with handſome young women procured from the Bayos, or Japaneſe lords, who thought it no diſgrace to their dignity to trade with ſtrangers in that ſort of commodity.

DISORDERLY HOUSES. See NUSANCE.

DISORDERLY *Perſons*. See VAGABONDS.

DISORIENTATED, from *dis*, and *oriens*, eaſt, a term applied to a thing that is turned, or removed from the eaſt, to which it was originally directed.

But the word is moſt frequently uſed in a figurative ſenſe, for the diſconcerting, or putting a man out of his way or element.

Andrew Marvel uſes the word diſoccidentated inſtead of diſorientated: Geneva had diſoccidentated our geographer.

DISPARAGEMENT, in *Law*, was uſed, in the old tenures, for the matching an heir, &c. in marriage, below his or her degree or condition; or againſt the rules of decency.

The word is a compound of the privative particle *dis*, and *par*, *equal*.

DISPART, in *Gunnery*, is uſed for ſetting a mark on the muzzle-ring of a piece of ordnance; ſo that a ſight-line, taken upon the top of the baſe ring againſt the touch-hole, by the mark ſet on or near the muzzle, may be parallel to the axis of the concave cylinder. The common way of doing which, is, to take the two diameters of the baſe ring, and of the place where the diſpart is to ſtand, and divide the difference between them into two equal parts, one of which will be the length of the diſpart, which is ſet on the gun with wax or pitch, or faſtened there with a piece of twine or marlin: but an inſtrument may be made to do it to all poſſible nicety. See *Line of* DIRECTION.

DISPART *Frontlet*. See FRONTLET.

DISPATCH, (from the French *dépêche*, which induced Johnſon to write it deſpatch,) is a letter on important ſtate affairs, ſent with particular care and expedition by a truſtworthy perſon, appointed for that ſpecial purpoſe. The perſons generally appointed to be the bearers of diſpatches in England are called king's meſſengers; in France and Germany, couriers. But when a letter of particular importance is confided in Germany to a poſtillion of the poſt-office, or to any ſpecial meſſenger ſent expreſs on horſeback, ſuch a perſon is called an eſtafette, corruptly eine ſtafette, in Engliſh an expreſs.

DISPAUPER. When any perſon by reaſon of his poverty, is admitted to ſue in *forma pauperis*; if afterwards, before the ſuit be ended, the ſame party have any land or perſonal eſtate fall to him, or that the court, wherein his ſuit is depending, think fit for that, or ſome other reaſon, to

to take away the privilege from him, he is then ſaid to be diſpaupered. See COSTS.

DISPENSARY, an inſtitution for the relief of the ſick poor with medical advice and neceſſary drugs, &c.; about twenty of which are eſtabliſhed in London, and ſupported by voluntary contributions. One or more phyſicians and ſurgeons attend daily at each diſpenſary, and preſcribe for the medicines, which are diſtributed gratuitouſly; and afterwards, thoſe patients who cannot meet the medical attendants at the inſtitution are *viſited* by them at their own habitations. In the latter reſpect, it is obvious, that a well conducted diſpenſary has the advantage over an hoſpital of adminiſtering comfort and relief to poor families, without mingling them with diſeaſed and dying ſtrangers, or ſeparating them from their neareſt relatives. But, as there are numerous caſes of individuals too poor to maintain themſelves during ſickneſs, or who are in a ſtate to need ſome chirurgical operation which cannot well be done at home, the practice of a diſpenſary muſt, in ſuch inſtances, give place to the accommodations of an hoſpital. (See HOSPITAL.) In ſome diſpenſaries three thouſand patients are relieved annually; ſo that, probably, not fewer than 40 000 poor perſons receive the benefit of thoſe humane eſtabliſhments every year in London alone!

Three diſpenſaries have been inſtituted by the college of phyſicians, the firſt of them in 1696, for the purpoſe of *vending* at prime coſt the medicines which were preſcribed for the ſick-poor; but they have been long ſince aboliſhed, and, indeed, are not now wanted, as medicines are furniſhed *gratis* at other diſpenſaries more recently eſtabliſhed. When we recollect, that, beſides theſe charitable inſtitutions, there are not leſs than twelve large hoſpitals in this metropolis, for the reception of the ſick and maimed, moſt of which are ſupported by voluntary ſubſcriptions; we cannot contemplate ſo much beneficence and fellow-feeling, without admiring the noble effects produced by the *Proteſtant* religion, and which are not found to the ſame extent in any other country.

DISPENSATION, in *Law, &c.* a permiſſion to do ſomething contrary to the ſtanding laws; or a relaxation, or ſuſpenſion of a law, on ſome juſt occaſion.

Some confound diſpenſation with equity; but they are very different things; for equity is only the correction, or modification, of a law which is too general; but a diſpenſation ſuſpends the obligation of the law itſelf, and can, therefore, be only given by the legiſlative power.

The king of France uſed to grant diſpenſations of age to ſome officers, to be admitted before the legal age: but the greateſt dealer in diſpenſations is the pope, who claims the office, *jure divino*, and extends it to every thing: indeed, the more ſober of the Romaniſts themſelves deny that he can give a diſpenſation for a thing contrary either to the divine law, or the law of nature, and confine him to what is contrary to poſitive laws, as to things relating to faſts, marriages, holding ſeveral benefices, &c. And even in theſe things they ſet bounds: thus, ſay they, a diſpenſation in the firſt degree of affinity, as that of father and daughter, brother and ſiſter, would be abuſive and null. But it is certain the papal ſee does not apprehend itſelf under any ſuch ſevere reſtrictions.

The right of giving diſpenſations they thus prove. It is certain the church has power to make laws: a power which the apoſtles themſelves exerciſed, and which their ſucceſſors have continued to exerciſe after them. Whoever can make a law, can annul it; and much more, can he diſpenſe with it in certain caſes: the church, then, may diſpenſe with the laws itſelf has made, and we find it to have done accordingly in all ages. See PRÆMUNIRE.

The archbiſhop of Canterbury has a power, by ſtat. 25 Hen. VIII. c. 21. of diſpenſing in any caſe, within the realm, wherein diſpenſations, not contrary to the law of God, were formerly granted by the ſee of Rome, as well to the king as to his ſubjects: but in extraordinary matters, or in a caſe that is new, the king and council are to be conſulted; and the diſpenſation muſt be confirmed under the broad ſeal: and during the vacancy of the archbiſhop's ſee, the guardian of the ſpiritualities may grant diſpenſations. Every biſhop, of common right, has the power of diſpenſing in common caſes.

DISPENSATIONS *for pluralities*. See CHAPLAIN and PLURALITY.

DISPENSATION *of the king*, makes a thing prohibited lawful to be done by the perſon that has it, though a thing evil in itſelf will not admit of a diſpenſation. When an offence wrongs none but the king, or if the ſuit is only the king's for the breach of a penal law, that is, not to the damage of a third perſon, the king may diſpenſe: but in caſe the ſuit is the king's, for the benefit of another, he cannot. It was formerly held, that the king might in many caſes diſpenſe with penal ſtatutes, and the exerciſe of this diſpenſing power was one of the moſt ignominious badges of ſlavery and engines of tyranny, which ever diſgraced and haraſſed this country. The claim and exerciſe of it are very ancient in England; and though it ſeems firſt to have been copied from papal uſurpations, it may be traced up as high as the reign of Henry III. The practice of diſpenſing with penal ſtatutes had ſo much prevailed, that parliament itſelf had more than once acknowledged this prerogative of the crown; particularly during the reign of Henry V., when they enacted the law againſt aliens, and alſo when they paſſed the ſtatute of proviſors. (Rot. Parl. 1 Hen. V.) However, in the reign of Richard II., the parliament granted the king only a temporary power of diſpenſing with the ſtatute of proviſors (Rot. Parl. 15 Rich. II.); a plain implication, ſays Mr. Hume, that he had not of himſelf ſuch a prerogative. In the 23d of Henry VI. a clauſe was inſerted in a ſtatute, by which the king was diſabled from granting a diſpenſation for a ſheriff's ſerving more than a year. Nevertheleſs the diſpenſing power prevailed in other caſes; and it was ſoon able, aided by the ſervility of the courts of judicature, even to overpower this ſtatute, which the legiſlature had evidently intended to ſecure againſt violation. In the reign of Henry VII. the caſe was brought to a trial before all the judges in the exchequer-chamber; and it was decreed that, notwithſtanding the ſtrict clauſe above-mentioned, the king might diſpenſe with the ſtatute. Many other diſpenſations of a like nature may be produced; not only ſuch as took place by intervals, but ſuch as were uniformly continued. In the 2d of James I., a new conſultation of all the judges was held upon a like queſtion; and this prerogative of the crown was again unanimouſly affirmed. (Coke's Rep. 7.) And it became an eſtabliſhed principle in Engliſh juriſprudence, that though the king could not allow of what was morally unlawful, he could permit what was only prohibited by poſitive ſtatute. Even the jealous houſe of commons, ſays Hume, which extorted the petition of right from Charles I., made no ſcruple, by the mouth of Glanville, their manager, to allow of the diſpenſing power in its full extent; and in the famous trial of ſhip-money, Holborne, the popular lawyer, had freely, and in the moſt explicit terms, made the ſame conceſſion. Sir Edward Coke, the great oracle of Engliſh law, had not only concurred with

with all other lawyers in favour of this prerogative, but ſeems even to believe it ſo inherent in the crown, that an act of parliament itſelf could not aboliſh it. (Rep. 12.) And he particularly obſerved, that no law can impoſe ſuch a diſability of enjoying offices as the king may not diſpenſe with, becauſe the king, from the law of nature, has a right to the ſervice of all his ſubjects. This diſpenſing power was exerciſed by Charles II. in his declaration of indulgence to diſſenters in 1672, but in the following year it was diſapproved and condemned by the houſe of commons. The diſſenters joined with other members of the houſe in diſavowing it, though it had been exerciſed in their favour. Alderman Love, member for the city of London, declared, "that he had rather go without his own deſired liberty, than have it in a way ſo deſtructive of the liberties of his country, and the proteſtant intereſt; and that this was the ſenſe of the main body of diſſenters:" at length the king recalled his declaration. King James II. diſpoſed to ſhew favour to the papiſts, and finding it impracticable to obtain a legal toleration in the circumſtances of the nation, in the year 1686, determined to attempt it by the diſpenſing power. On this occaſion many pamphlets were diſperſed in favour of liberty of conſcience; and ſir Roger l'Eſtrange, with many other mercenary writers, were employed to maintain, that a power in the king, to diſpenſe with the laws, is law. Moreover, it was reſolved, to have the determination of the judges on this queſtion: and they all (except one) gave it as their opinion, 1. "That the laws of England were the king's laws 2. That it is an inſeparable branch of the prerogative of the kings of England, as of all other ſovereign princes, to diſpenſe with all penal laws in particular caſes, and on particular occaſions. 3. That of theſe reaſons and neceſſity the king is ſole judge. 4. That this is not a truſt now inveſted in, and granted to the preſent king, but the ancient remains of the ſovereign power of the kings of England, which was never yet taken from them, nor can be." Accordingly, a diſpenſation, or licence office, was ſet up, where all who applied might have an indulgence, paying only fifty ſhillings, for themſelves and their families. Many non-conformiſts, now careſſed by the court for very obvious reaſons, who had been proſecuted for conventicles, took out theſe licences, which not only ſtopped all proceſſes that had been commenced, but gave them liberty to go publicly to meetings for the future. Whatever topics lawyers might find to defend James's diſpenſing power, the nation thought it dangerous, if not fatal, to liberty; and his reſolution of exerciſing it may, on that account, be eſteemed no leſs alarming, than if the power had been founded on the moſt recent and flagrant uſurpation. However, he was determined to perſevere; nor was he deterred by the reflection, that this ſcheme of indulgence had already failed in the preceding reign, and that in ſuch a government, as that of England, it was not ſufficient that a prerogative be approved of by ſome lawyers and antiquaries: if it was condemned by the general voice of the nation, and yet was ſtill exerted, the victory over national liberty was no leſs ſignal than if obtained by the moſt flagrant injuſtice and uſurpation. Nevertheleſs in the following year, *viz.* 1687, he iſſued his declaration for liberty of conſcience; and announced it to be his intention, from time to time, to grant his royal diſpenſation to all his ſubjects to be employed in any office, or place of truſt, either civil or military, under his government. A ſimilar declaration was ſent to Scotland. Some diſſenters of the ſeveral denominations, who were now admitted to ſerve in all offices of profit and truſt, were thankful for their liberty, and concurred with others in addreſſing his majeſty in higher ſtrains than ſome of their elder and more cautious miniſters approved. Many of the moſt reſpectable refuſed to join in them; and biſhop Burnet admits, that few concurred in theſe addreſſes: and that the perſons who preſented them were mean and inconſiderable. The diſſenters, in general, both dreaded and deteſted the diſpenſing power, whatever preſent benefit might redound from it to themſelves. Means were uſed for electing a parliament which would ſanction the king's declaration of indulgence, and cauſe it to paſs into a law; but amongſt many others, who were indiſpoſed to concur in the court meaſures, the diſſenters, though they had been peculiarly favoured, manifeſted either total indifference or averſion. Concerned for the proteſtant religion, and dreading the effects of the king's bigotted attachment to popery, they choſe to truſt their liberty to the mercy of their proteſtant brethren, rather than receive a legal ſecurity of it under a popiſh government. Their conduct diſobliged the king to a very high degree, and he ſaid, that "the diſſenters were an ill-natured ſort of people that could not be gained."

The king, finding little hopes of ſucceſs, delayed the ſummoning of a parliament, and proceeded ſtill in the exerciſe of his *illegal* and arbitrary authority. In 1688, he publiſhed a ſecond declaration of indulgence, almoſt in the ſame terms with the former; and he ſubjoined an order that, immediately after divine ſervice, it ſhould be read by the clergy in all the churches. The clergy determined not to comply with the royal mandate; and in order to encourage them in this reſolution, ſix prelates concerted the form of a petition to the king, in which, amongſt other things, they repreſented, that, as the declaration of indulgence was founded on a prerogative, formerly declared illegal by parliament, they could not, in prudence, honour, or conſcience, ſo far make themſelves parties, as the diſtribution of it all over the kingdom would be interpreted to amount to. They therefore beſought the king, that he would not inſiſt upon their reading the declaration. The conſequence is well known. The biſhops were ſummoned before the council and committed to the Tower. It is beſides our purpoſe in this place to give in detail thoſe farther violent proceedings of king James, which accelerated the revolution. But adverting to the immediate ſubject of this article we ſhall only obſerve, that by ſtatute 1 W. & M. c. 2. it is declared, that the ſuſpending or diſpenſing with laws by regal authority, without the conſent of parliament, is illegal: it is alſo a maxim in law, that it requires the ſame ſtrength to diſſolve as to create an obligation. See Blackſt. Com. vol. i. and vol iv. Neal's Hiſt. of the Puritans, vol. i. See PREROGATIVE.

DISPENSATION *by non obſtante*. See NON-OBSTANTE.

DISPENSATION, in *Pharmacy*, the diſpoſition and arrangement of ſeveral medicines, either ſimple or compound, all weighed in their proper doſes, or quantities, in order to be employed in the making of a compoſition.

DISPENSATIONS, *Divine*, in *Theology*, otherwiſe called the *works* and *ways of God*, denote thoſe ſchemes or methods which are deviſed and purſued by the wiſdom and goodneſs of God, in order to manifeſt his perfections and will to mankind, for the purpoſes of their inſtruction, diſcipline, reformation, and advancement in rectitude of temper and conduct, in order to promote their happineſs. Theſe are the grand ends of the divine diſpenſations; and in their aptitude to promote theſe ends conſiſts their peculiar excellence. The works or conſtitutions of nature are, in a general ſenſe, divine diſpenſations, by which God condeſcends to diſplay to us his being and attributes, and thus to lead us to the acknowledgment, adoration, love, and dutiful obedience of our creator, father, and benefactor. But beſides the general

conſtitution of nature, there is a variety of other diſpenſations, which more immediately pertain to mankind, and in which they are more eſpecially intereſted. Such are their being born of parents for ſupplying the ſeveral generations of the world, whence reſult ſundry relations and duties; their being ſuſtained by food, covered and ſheltered by clothes and habitations, healed by phyſicians, and taught by the learned and ſkilful; their forming of ſocieties for mutual convenience and comfort; and the inſtitution of government, or the ſubordination of ſome to the authority of others, for preſerving good order, for the protection of virtue, and the reſtraint and puniſhment of vice. Moreover, wars, peſtilence, famine, earthquakes, perſonal and natural calamities, and ſimilar events, may be reckoned among the divine appointments or diſpenſations; ſome of which are deſigned for the exerciſe of our rational and moral powers in a courſe of right conduct; ſome for diſcipline, correction, and reformation; but none merely for deſtruction, except where reformation cannot be effected. But the ſacred ſcriptures reveal and record other diſpenſations of divine providence, which have been directed to the promotion of the religious principles, moral conduct, and true happineſs of mankind. Theſe have varied in ſeveral ages of the world, and have been adapted by the wiſdom and goodneſs of God to the circumſtances of his intelligent and accountable creatures. In this ſenſe the various revelations which God has communicated to mankind at different periods, and the means he has uſed, as occaſion has required, for their diſcipline and improvement, have been juſtly denominated divine diſpenſations. Accordingly, we read in the works of theological writers of the various diſpenſations of religion, as they exiſted before and after the fall of man, that of the patriarchs, that of Moſes, that of Chriſt, called the diſpenſation of grace, the perfection and ultimate object of every other; all of which were adapted to the conditions of the human race at theſe ſeveral periods; all of theſe in regular ſucceſſion mutually connected and preparatory one to the other; and all ſubſervient to the deſign of meliorating the world, and of contributing to the perfection and happineſs of its rational and moral inhabitants. See COVENANT and REVELATION.

DISPENSATORY, in *Medicine*, is ſynonymous to the word *Pharmacopœia*, and ſignifies a collection of formularies or directions for the uſe of apothecaries. Many private practitioners have written and publiſhed diſpenſatories; but thoſe which are of greateſt authority, have been compoſed by colleges or authorized bodies of medical men. Thus, in the United Kingdom, we have the London, the Edinburgh, and the Dublin pharmacopœia or diſpenſatory; the former being of moſt authority in England and Wales, the next in Scotland, and the laſt in Ireland. Nevertheleſs, it is lawful for apothecaries to uſe either or all of them, as they may judge fit; only, it is required, when they deviate from the eſtabliſhed pharmacopœia, that they do ſo "by the ſpecial direction or preſcription of ſome learned phyſician." (See PHARMACOPOEIA.) The completeſt work of this kind now extant in this kingdom, is that of Dr. Duncan, Jun., entitled, "The Edinburgh New Diſpenſatory," which includes the lateſt editions of the three authorized pharmacopœias in one volume.

Although the apothecaries of London are enjoined, under his Majeſty's diſpleaſure, to keep all the ſimple and compound remedies preſcribed in the pharmacopœia of the royal college of phyſicians, and not to vary from them of their own accord, it is a fact that all the apothecaries do nevertheleſs preſcribe daily for their patients, without regarding the formulæ of the college! But a much more lamentable fact is this, that any perſon who chuſes, however ignorant and unſkilful he is in phyſic, may ſet up as a druggiſt or an apothecary, and then may practiſe as a phyſician, *i. e.* he may attend the ſick and adminiſter whatever medicines he will; which, indeed, is done continually by hundreds of illiterate men in the metropolis and elſewhere, without being puniſhable by law! The vaſt quantities of licenſed quack medicines ſold annually, are compounded by ignorant men or women (with very few exceptions), to the great profit of the revenue and the certain detriment of his majeſty's ſubjects; proving how little avail are the ſtatutes of the college for preventing pharmaceutical abuſes, &c.! The firſt diſpenſatory, ſays Beckmann, (Hiſt. Invent. vol. ii.) was drawn up by Valerius Cordus, or at leaſt his was the firſt made known by the approbation of public magiſtrates. Haller has remarked one older; but it is now known only from the title mentioned by Maittaire. (Biblioth. Bot. i. p. 244.) Cordus, however, appears to have firſt uſed the word *diſpenſatorium* for a collection of receipts, containing directions how to prepare the medicines moſt in uſe. Some have ſaid that the book of Cordus was improved and enlarged by Matthiolus. But Beckmann ſays, that this is a miſtake, and that the error ſeems to have ariſen from the Chriſtian name of Matthias Lobelius, which ſtands in the title of ſome editions, becauſe his annotations are added to them.

DISPERIS, in *Botany*, (from δις, *double*, and πηρα, *a pouch*, becauſe the two lateral leaves of the calyx are each furniſhed with a little ſpur-like bag or cavity, which makes a part of the generic character,) Swartz. Orchid. 38. t. 1. f. F. Willd. Sp. Pl. v. 4. 59. Claſs and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*.

Gen. Ch. *Cal.* Perianth of three leaves; the upper one erect and vaulted, forming a ſort of helmet with the two petals; the two lateral ones ſpreading horizontally, each furniſhed with a central pouch or ſpur pointing downwards. *Cor.* Petals two, ſhorter than the calyx, dilated upwards, abrupt, ſheltered by the upper calyx-leaf. Nectary or lip proceeding from the baſe of the ſtyle, erect, tapering at the lower part, attached to the organs of impregnation, reflexed at the top under the helmet. *Stam.* and *Piſt.* Germen inferior, oblong, ſomewhat obovate; ſtyle very ſhort; ſtigma in front near the anther. Anther attached to the top of the ſtyle, erect or reclining, oblong, of two cells, covered with a veil which bears at its margin on each ſide in front, a little cartilaginous ſpiral appendage; pollen oblong, glutinous, its ſtalks glued to the tips of the appendages of the veil. *Peric.* Capſule of one cell, with three angles and three valves, burſting at the angles. *Seeds* numerous, minute, roundiſh, each with a membranous integument.

Eſſ. Ch. Calyx ſpreading; its two lateral leaves horizontal, ſomewhat ſpurred. Lip from the baſe of the ſtyle, erect, connected with the organs of impregnation. Anther covered with a veil bearing two ſpiral appendages in front.

Five ſpecies of this genus are enumerated by Swartz copied by Willdenow. 1. D. *capenſis* (Arethuſa capenſis; Linn. Supp. 405. Thunb. Prod. 3.), a native of the Table mountain at the Cape of Good Hope. "Stalk bearing two lanceolate leaves, and one flower." This is a pretty plant, about a foot high, with a purple flower remarkable for its long-pointed ſpreading calyx. 2. D. *villoſa*. (Arethuſa villoſa; Linn. Suppl. 405. Thunb. Prod. 3.) "Stem with two leaves and one flower. Bractea and germen hairy. Leaves ovate inclining to heart-ſhaped, ſmooth beneath, fringed at the margin." This grows alſo at the Cape, and is ſaid by the younger Linnæus to look like a *Commelina*. 3. D. *cucullata*. Swartz. Orchid. 40. Willd. Sp.

Sp. Pl. v. 4. 59. "Stem with two leaves and one flower. Germen ſmooth. Leaves oblong, downy beneath, as well as the bractea." Native of the Cape. 4. D. *ſecunda*. (Arethuſa ſecunda; Thunb. Prod. 3. Ophrys circumflexa; Linn. Sp. Pl. 1344.) "Stem with two linear leaves, and many flowers leaning one way." This grows alſo at the Cape, and bears ſeveral yellowiſh green flowers, whoſe white veils and their twiſted appendages are very conſpicuous. 5. D. *cordata*. Swartz. Orchid. 41. Willd. 60. "Stem with two heart-ſhaped ſmooth leaves, and many ſeparate flowers." Native of the iſland of Mauritius. *Flowers* yellowiſh, four or five in a ſort of corymbus, with an ovate bractea to each. To theſe we are enabled to add a non-deſcript ſpecies. 6. D. *oppoſitifolia*. "Stem with two oppoſite ovate ſmooth leaves, and ſeveral bracteated flowers." Native of the iſle de Bourbon, communicated by Dr. Smith from the Linnæan herbarium. *Root* tuberous. *Stem* a ſpan high. *Leaves* above an inch long, oppoſite, about the middle of the ſtem, ſpreading, obſcurely five-ribbed. *Flowers* three or four in a bracteated ſpike, yellowiſh. *Bracteas* elliptical.

DISPERSE, in *Military Language*. To diſperſe a body of men, in the heat of an engagement, and to rally them, ſo as to take advantage of an enemy ſcattering in purſuit, or leaving a ſtrong poſt for that purpoſe, is a ſtratagem which has been reſorted to at times with peculiar ſucceſs. Being, however, extremely hazardous, it ſhould only be practiſed with well diſciplined troops, and by previous notice; when the ſignal to rally ſhould likewiſe be communicated to every individual. In order to deceive the enemy more effectually, it is common to attack him in his entrenchments with great ſhew of vigor, and in the height of the conflict to beat the *retreat*; on this the aſſailants ſhould retire in ſeeming diſorder, but with ſtudied attention to the object in view. If it be practicable to lead the enemy beyond ſome old building, or coppice, or hedge-row, behind which ſome men could be placed in ambuſh, the effect will be conſiderably encreaſed; both by encreaſing the ſurprize, and panic, and by placing the enemy between two fires. It ought, however, to be always carried in mind, that when once ſoldiers turn their backs, they loſe ſomething of their confidence; and that it is extremely difficult to get them to face about at the proper moment. This device is beſt calculated for rangers, rifle-men, and other light corps.

DISPERSION *of Light*, in *Optics*, denotes the enlargement of a pencil or beam of light, which is produced by its paſſage from one medium into another, and this enlargement ariſes from the nature of the medium; but there is an enlargement of light, which ariſes from the form of the medium, and which is not comprehended under the denomination of the preſent article. We ſhall briefly endeavour to point out the diſtinction.

When a beam of light, (ſuch, for inſtance, as proceeds from the ſun, and comes into a room through a hole in a window ſhutter) is received upon a concave lens, and a ſheet of paper is placed to receive it on the other ſide of, and at a little diſtance from, the lens; the luminous ſpot, which is thereby formed upon the paper, will be found much larger in diameter than the diameter of the hole in the ſhutter through which the light enters; the reaſon of which is, that on account of the concavity of the ſurface of the lens, every part of the beam of light, excepting the very axis of it, falls obliquely upon the ſurface of the lens, and is bent from the axis of it, in conſequence of which it, the beam of light, proceeds in a diverging direction from the lens to the paper, and neceſſarily forms an enlarged ſpot upon the latter. Now this enlargement, being the effect of the peculiar figure of the lens, is not conſidered under the preſent article.

When a beam of light paſſes not in a perpendicular, but in an oblique direction from one medium into another medium of a different nature, ſuch as from air into water, or into glaſs, &c. its ſtraight direction is deſtroyed, *viz.* it is bent to a certain degree, and this bending is called the *refraction of light*; but beſides its being bent, the beam of light is ſpread in a ſectoral form, and is divided into coloured ſtripes (ſee the articles LIGHT and REFRACTION.) Now this ſpreading, which ſeems to ariſe from the nature of the medium, is called the *diſperſion*, or *diſſipation, of light*, and is the object of our preſent conſideration. The following illuſtration will render the nature of it more evident.

Let H (*Plate* IV. *Optics*, *fig.* 7.) repreſent a ſmall beam of the ſun's light, which paſſes through the tube I, and falls obliquely at C, upon the ſurface A D, of the refracting medium A B D G, be it water, or glaſs, or other tranſparent ſubſtance. Let a circle of any diameter be drawn round the centre C, cutting the beam of light at O. Draw the perpendicular H N through C. The beam of light, by its falling obliquely upon the ſurface of the water at C, will be refracted, *viz.* will be bent, from its ſtraight direction C P, into the more inclined direction C *s*, and will at the ſame time be ſpread into the ſectoral ſhape *r* C *t*. which is called the *diſperſion of the light*. This ſector *r* C *t* is itſelf divided into ſmaller ſectors of different colours; *viz.* next to the upper line C *r*, the colour is red, and thence the light gradually degenerates into orange, yellow, green, blue, indigo, and violet, which is neareſt to the lower boundary C *t*. All this may be perceived by placing a white ſurface at the bottom of, or within, the refractive medium A B D G.

From the points O, *r*, *s*, and *t*, let perpendiculars be dropped on the line H N; then C *s*, which is drawn through the middle of the angle *r* C *t*, is the mean direction of the refracted light, and *s e* is its ſine, or the *ſine of the mean angle of refraction*; O M being the ſine of the angle of incidence, *r w* and *t q* are the ſines of the extremes, of which *t q* is the *ſine of the moſt refrangible* colour, and *r w* the *ſine of the leaſt refrangible* colour.

It has been found, that through the ſame medium, the angle of diſperſion is always proportionate to the mean angle of refraction, and, of courſe, when the mean angle of refraction is very ſmall, then the angle of diſperſion *r* C *t*, muſt be much ſmaller, in which caſe the different colours cannot be diſtinguiſhed; but when the angle of incidence O C M, and conſequently the mean angle of refraction *s* C N, are conſiderably larger; then the angle *r* C *t* of diſperſion will alſo be large enough to exhibit the above-mentioned colours.

Different refractive media have different diſperſive powers; for inſtance, the angle of incidence O C H, remaining the ſame, not only the mean angle of refraction *s* C N will vary according as the refractive medium A B D G is water, or glaſs, or oil, or diamond, &c. but the angle of diſperſion *r* C *t* will alſo vary. And in ſome refracting media, the mean angle of refraction is larger, whilſt the angle of diſperſion is ſmaller; in other refracting media the mean angle of refraction is ſmaller, whilſt the angle of diſperſion is larger. In ſhort, the knowledge of the mean refractive power of a given ſubſtance will not enable us to determine its diſperſive power, and *vice verſâ*.

Sir I. Newton, who made the important diſcovery of the different refrangibility of the rays of light, which converted the white ſolar light into the colours of the rainbow, when that light was made to paſs obliquely from one tranſparent medium into another, had not the leaſt ſuſpicion of the

different diſperſion ariſing from the different natures of the media; and he imagined that the refrangibility of the extreme rays might be determined, if that of the mean was given. Or, in other words, that if the angles of refraction in different media were alike, the angles of diſperſion in thoſe media would likewiſe be alike; but it was reſerved for Mr. Dollond to ſhew the fallacy of this ſuppoſition, which was conſidered as true by all the philoſophers of his time. Mr. Dollond began to ſuſpect the truth of it, and in the year 1757 he commenced a courſe of laborious experiments which confirmed him in his ſuſpicion, gradually ſhewed him that different tranſparent ſubſtances were endowed with different diſperſive powers, ſhewed him the preciſe limits of thoſe powers, and finally led him to make the capital diſcovery of the achromatic teleſcope, which depends upon the different diſperſive powers of different ſorts of glaſs, and which will doubtleſs tranſmit his name to the lateſt poſterity. Mr. Dollond having thus ſhewn the important uſes to which the different diſperſive powers of tranſparent ſubſtances were applicable, ſeveral ingenious perſons readily took the ſubject in hand, and endeavoured to aſcertain the diſperſive properties of various bodies, to ſimplify the method of determining that property, and to apply it to optical uſes. The ſimpleſt, and, at the ſame time, the accurate method of aſcertaining the preciſe diſperſive power of a given ſubſtance, is to form a priſm of it, to expoſe it to a beam of ſolar light which enters a dark room through a hole, and then to meaſure, as exactly as poſſible, the angle of refraction, and the breadth of the ſpectrum upon a ſcreen placed at a given diſtance from the priſm; and from theſe particulars the angle of diſperſion in proportion to the angle of refraction may be eaſily deduced; thus, by making priſms of different ſubſtances, but exactly of the ſame refractive angle, and placing them ſucceſſively in the like circumſtances, the peculiar diſperſive powers of thoſe ſubſtances may be aſcertained. Mr. Euler, who gives particular inſtructions reſpecting the performance of this operation, adviſes to make uſe of priſms with very large refracting angles, not leſs than 70 degrees. The Philoſophical Tranſactions for the year 1802, art. xii. contains the account of a new method of examining the refractive and diſperſive powers by means of priſmatic reflection, by Dr. W. H. Wollaſton; but as the principal uſe of this method is for aſcertaining the refractive powers of ſubſtances, the reader will find it deſcribed under the article REFRACTION. With reſpect to the diſperſive powers, Dr. Wollaſton did not meaſure them with accuracy, nor indeed does his method, without ſome farther improvement, ſeem capable of determining theſe powers with great preciſion. We ſhall in the ſequel add his liſt of diſperſive powers, ſuch as it is; but we ſhall premiſe a liſt of thoſe ſubſtances, whoſe diſperſive powers have been aſcertained with greater preciſion.

TABLE of the diſperſive Powers of various tranſparent Subſtances, in compariſon of the diſperſive Power of Water, which is reckoned 100.

	Diſperſion.
White flint-glaſs, of the ſpecific gravity 3.29,	180
Glaſs made of minium; *viz.* red-lead, and flint, in the proportion of M. 3, F. 1,	709
M. 2, F. 1,	524
M. 1, F. 1,	482
M. ¾, F. 1,	325
M. ½, F. 1,	265
M. ¼, F. 1,	200
Common plate-glaſs, or coach-glaſs, ſp. gr. 2.76,	165
Crown-glaſs, ſp. gr. 2.52,	148
Brazil pebble, ſp. gr. 2.62,	159
Glaſs tinged red by means of gold, for enamel,	290
Glaſs of *Saint Gobin*, in France,	149
Diamond,	286
Rock-cryſtal,	121
Another ſpecimen of the ſame,	124
Iſland-cryſtal,	169
Another ſpecimen of the ſame,	233
Water,	100
Water ſaturated with common ſalt,	122
Solution of ſal ammoniac, or of muriated ammonia,	134
Nitric acid,	154

Dr. Wollaſton's Table of diſperſive Powers, reſpecting which he ſays,

"I have endeavoured to reduce the ſeveral ſubſtances, thus examined, to one table; but as the limits of colour are in few inſtances ſufficiently well defined for accurate menſuration, I have not attempted to add any numerical eſtimate of their powers, but have merely aſcertained the order in which they ſucceed each other."

In this order the ſubſtances now follow:

Sulphur,	Amber,
Glaſs of lead, (⅓ ſand,)	Diamond,
Balſam of Tolu,	Alum,
Oil of ſaſſafras,	Plate-glaſs, Dutch,
Muriate of antimony,	Plate-glaſs, Engliſh,
Guaiacum,	Crown-glaſs,
Oil of cloves,	Ruby, (ſpinelle,)
Flint-glaſs,	Water,
Colophony,	Sulphuric acid,
Canada balſam,	Alcohol,
Oil of amber,	Sulphate of barytes,
Jargon,	Selenite,
Oil of turpentine,	Rock-cryſtal,
Copal,	Sulphate of potaſh,
Balſam of Capivi,	White ſapphire,
Anime,	Fluor ſpar.
Iceland ſpar,	

Mr. Zeiher of Peterſburgh, who compoſed the ſix kinds of glaſs made with flint and minium, and examined their diſperſive powers, which are ſtated at the commencement of the firſt table, willing to give a ſuperior or more uſeful conſiſtence to thoſe glaſſes, tried to mix alkaline ſalts with them; but he was much ſurpriſed to find that this mixture greatly diminiſhed the mean refraction, almoſt without making any change in the diſperſion. After many trials, he, at length, obtained a kind of glaſs, greatly ſuperior to the flint-glaſs uſed by Dollond, with reſpect to the conſtruction of teleſcopes, ſince it occaſioned three times as great a diſperſion of the rays as common glaſs, at the ſame time that the mean refraction was only as 1.61 to 1. (Ac. Berl. 1766.) Having now ſtated all the moſt eſſential obſervations which have been made by various ingenious philoſophers reſpecting the powers of diſperſing the rays of light by a variety of ſubſtances, the reader may probably expect ſome information relative to the cauſe of that power, or rather to the cauſe which renders that power greater in one body than in another. Were the diſperſive power proportional to the refractive power, the phenomenon would occaſion no wonder; but ſince there ſeems to be no correſpondence whatever between the one and the other, the human mind is naturally led to make the above-mentioned enquiry. It is not, however, in our power to give our readers any ſatisfactory information about it. The inveſtigations of various philoſophers have not furniſhed any thing more than

conjectures. Some have attributed the diſperſion of rays of different colours to a ſort of elective attraction in the tranſparent body. "But," as Dr. Thomas Young juſtly obſerves, "an elective attraction of this kind is a property foreign to mechanical philoſophy, and when we uſe the term in chemiſtry, we only confeſs our incapacity to aſſign a mechanical cauſe for the effect, and refer to an analogy with other facts, of which the intimate nature is perfectly unknown to us."

The volume of the Philoſophical Tranſactions for the year 1802, contains a paper of the above-mentioned gentleman, Dr. Thomas Young, on a peculiar production of colours. In that paper, Dr. Young offers an hypotheſis, which is the neareſt that has been offered, reſpecting the diſperſive powers of bodies, and with which we ſhall conclude this article. "The colours," he ſays, "of mixed plates ſuggeſt to me an idea, which appears to lead to an explanation of the diſperſion of colours by refraction, perhaps more ſimple and ſatisfactory than that which I advanced in the laſt Bakerian lecture. We may ſuppoſe that every refractive medium tranſmits the undulations conſtituting light in two ſeparate portions, one paſſing through its ultimate particles, and the other through its pores; and that theſe portions reunite continually, after each ſucceſſive ſeparation, the one having preceded the other by a very minute but conſtant interval, depending on the regular arrangement of the particles of a homogeneous medium. Now, if theſe two portions were always equal, each point of the undulations, reſulting from their reunion, would always be found half-way between the places of the correſponding point in the ſeparate portions; but ſuppoſing the preceding portion to be the ſmaller, the newly combined undulation will be leſs advanced than if both had been equal, and the difference of its place will depend, not only on the difference of the lengths of the two routes, which will be conſtant for all the undulations, but alſo on the law and magnitude of thoſe undulations; ſo that the larger undulations will be ſomewhat further advanced after each reunion than the ſmaller ones, and the operation recurring at every particle of the medium, the whole progreſs of the larger undulations will be more rapid than that of the ſmaller; hence the deviation, in conſequence of the retardation of the motion of light in a denſer medium, will of courſe be greater for the ſmaller than for the larger undulations. Aſſuming the law of the harmonic curve for the motions of the particles, we might, without much difficulty, reduce this conjecture to a compariſon with experiment; but it would be neceſſary, in order to warrant our concluſions, to be provided with accurate meaſures of the refractive and diſperſive powers of various ſubſtances, for rays of all deſcriptions."

DISPERSION *of Mankind*, in the *Hiſtory of the World*, was occaſioned by the confuſion of tongues, and took place in conſequence of the overthrow of Babel at the birth of Peleg; whence he derived his name: and it appears by the account given of his anceſtors, Gen. chap. xi. 10—16. to have happened in the 101ſt year after the flood, B. C. 2247, according to the Hebrew chronology, and by the Samaritan computation in the 401ſt. However, various difficulties have been ſuggeſted by chronologers concerning the true era of this event. Sir John Marſham and others, in order to reconcile the Hebrew and Egyptian chronologies, maintain a diſperſion of mankind before the birth of Peleg: others, unable to find numbers ſufficient for the plantation of colonies in the ſpace of 101 years, according to the Hebrew computation, fix the diſperſion towards the end of Peleg's life, thus following the computation of the Jews, adopted by St. Jerom, and ſeveral of the Chriſtian chronologers: Petavius aſſigns the 153d year after the flood; Cumberland, the 180th; and Uſher, though he generally refers it to the time of Peleg's birth, in one place aſſigns the 131ſt after the flood for this event. Mr. Shuckford ſuppoſes the diſperſion to have been gradual, and to have commenced with the ſeparation of ſome companies at the birth of Peleg, and to have been completed thirty-one years after. According to the calculation of Petavius, the number of inhabitants on the earth at the birth of Peleg amounted to 32,768; Cumberland makes them 30,000; Mr. Mede ſtates them at 7000 men, beſides women and children; and Mr. Whiſton, who ſuppoſes that mankind now double themſelves in four hundred years, and that they doubled themſelves between the deluge and the time of David in ſixty years at a medium, when their lives were ſix or ſeven times as long as they have been ſince, by his computation, produces about 2389, a number much too inconſiderable for the purpoſes of ſeparating and forming diſtinct nations. This difficulty induced Mr. Whiſton to reject the Hebrew, and to adopt the Samaritan chronology, as many others have done; which, by allowing an interval of 401 years between the flood and the birth of Peleg, furniſhes, by the laſt mentioned mode of computation, more than 240,000 perſons. Uſher is of opinion, (Chron. Sacr. p. i. c. 5.) that in the 102d year after the flood, mankind might have increaſed to the number of 388,605 males, and as many females. This uncommon increaſe he aſcribes to an extraordinary fecundity implied in that repeated command or bleſſing, "Increaſe and multiply, and fill the earth." But a much ſmaller number than this would have been ſufficient. Marſh. Can. Chron. ſec. 1. Petav. Doctrin. Temp. lib. ix. c. 14. Cumb. Orig. Gent. Antiq. p. 142—154. Uſher ad A. M. 1757 & 1787. Whiſton's View Chron. O. T.

As to the manner of the diſperſion of the poſterity of Noah from the plain of Shinar, it was undoubtedly conducted with the utmoſt regularity and order. The ſacred hiſtorian informs us, that they were divided in their lands, every one according to his tongue, according to his family, and according to his nation; Gen. x. 5, 20, 31; and thus, as Mr. Mede obſerves, they were ranged according to their nations, and every nation was ranged by their families, ſo that each nation had a ſeparate lot, and each family in every nation. The following abſtract will ſerve to give a general idea of their reſpective ſettlements: Japhet, Noah's eldeſt ſon, had ſeven ſons, *viz.* Gomer, whoſe deſcendants inhabited thoſe parts of Aſia, which lie upon the Ægean ſea and Helleſpont northward, containing Phrygia, Pontus, Bithynia, and a great part of Galatia: the Galatians, according to Joſephus, were called Gomeræi; and the Cimmerii, according to Herodotus, occupied this tract of country: and from theſe Gomerians, Cimmerii or Celts, Mr. Camden derives our ancient Britons, who ſtill retain the name Cymro or Cymru: Magog, the ſecond ſon of Japhet, was probably the father of the Scythians on the eaſt and north-eaſt of the Euxine ſea: Madai planted Media, though Mr. Mede aſſigns Macedonia to his ſhare: Javan was the father of the Grecians about Ionia, whoſe country lies along upon the Mediterranean ſea; the radicals of Javan and Ionia, being the ſame יון: to Tubal and Meſhech belonged Cappadocia, and the country which lies on the borders of the Euxine ſea; and from them, migrating over the Caucaſus, it is ſuppoſed the Ruſſians and Muſcovites are deſcended: and Tiras occupied Thrace. The ſons of Shem were five: Elam, whoſe country lay between the Medes and Meſopotamians, and

was called by the Gentile writers Elymais; and Joſephus calls the Elamites the founders of the Perſians: Aſhur, who was driven out of Shinar by Nimrod, afterwards ſettled in Aſſyria, and there built Nineveh, and other cities: Arphaxad, who gave name to the country which Ptolemy calls Arraphacitis, a province of Aſſyria, though Joſephus makes him the father of the Chaldees: Lud, who inhabited, and, as ſome ſay, gave name to the country of Lydia, about the river Mæander, remarkable for its windings, in Aſia Minor: and Aram, the father of the Aſſyrians, who inhabited Meſopotamia and Syria, comprehending the countries weſtward of Aſſyria, as far as the Mediterranean ſea; within or bordering on this country of Aram, his four ſons probably ſettled. Ham, the youngeſt ſon of Noah, had four ſons, *viz.* Cuſh, whoſe poſterity ſpread into the ſeveral parts of Arabia, over the borders of the land of Edom, into Arabia Felix, up to Midian and Egypt: Mizraim, the father of them who inhabited Egypt, and other parts of Africa: Phut, to whom Bochart aſſigns the remaining part of Africa, from the lake Tritonides to the Atlantic ocean, called Libya: and Canaan, to whom belonged the land of Canaan, whence the Phœnicians derived their origin.

Upon this diſtribution of Noah's poſterity, we ſhall only obſerve, that the Deity preſided over all their counſels and deliberations, and that he guided and ſettled all mankind, according to the dictates of his all-comprehending wiſdom and benevolence. To this purpoſe, the ancients themſelves, according to Pindar, (Olymp. od. vii.) retained ſome idea, that the diſperſion of men was not the effect of chance, but that they had been ſettled in different countries by the appointment of Providence. (See Gen. xi. 8, 9. Deut. xxii. 8.)

This diſperſion, and that confuſion of languages with which it originated, was intended, by the counſel of an all-wiſe Providence, to counteract and defeat the ſcheme which had been projected by the deſcendants of Noah, for maintaining their union, and, of courſe, their ſuperiority and pre-eminence; implied in their propoſing to make themſelves a *name*, שם, which Schultens (in Job. i. 1.) derives from the Arabic verb שמה, or שבא, to be high, elevated, or eminent. Thus, they might think, by building a lofty tower, to keep off all that ſhould attempt to break in upon them, and to intimate to all future generations, that they were the true original governors, to whom all mankind ought to be in ſubjection. By this ſcheme, which ſeems to have been a project of ſtate policy, for keeping all men together under the preſent chiefs and their ſucceſſors, a great part of the earth muſt, for a long time, have been uninhabited, and over-run with wild beaſts. The bad effects which this project would have had upon the minds, the morals, and religion of mankind, was, probably, the chief reaſon why God interpoſed to fruſtrate it as ſoon as it was formed. It had manifeſtly a direct tendency to tyranny, oppreſſion, and ſlavery. Whereas in forming ſeveral independent governments by a ſmall body of men, the ends of government, and the ſecurity of liberty and property, would be much better attended to, and more firmly eſtabliſhed; which, in fact, was really the caſe; if we may judge of the reſt by the conſtitution of one of the moſt eminent, the kingdom of Egypt. (Gen. xlvii. 15—27.) The Egyptians were maſters of their perſons and property, till they ſold them to Pharoah for bread; and then their ſervitude amounted to no more than the fifth part of the produce of the country, as an annual tax payable to the king.

By this event, conſidered as a wiſe diſpenſation of Providence, bounds were ſet to the contagion of wickedneſs; evil example was confined, and could not extend its influence beyond the limits of one country; nor could wicked projects be carried on, with univerſal concurrence, by many ſmall colonies, ſeparated by the natural boundaries of mountains, rivers, deſerts, ſeas, and hindered from aſſociating together by a variety of languages, unintelligible to each other. Moreover, in this diſperſed ſtate, they could, whenever God pleaſed, be made reciprocal checks upon each other, by invaſions and wars; which would weaken the power, and humble the pride of corrupt and vicious communities. This diſpenſation was, therefore, properly calculated to prevent a ſecond univerſal degeneracy; God dealing in it with men as rational agents, and adapting his ſcheme to their ſtate and circumſtances. Mede's Works, vol. i. diſc. 50. p. 276, &c. Bochart, Phaleg. lib. iii. & iv. Patrick in loc. Shuckford's Conn. vol. i. book i. and Un. Hiſt. vol. i. part 3. book i. chap. 2. § 6.

Dr. Bryant has advanced a new hypotheſis on this ſubject, and ſupported it with his uſual acuteneſs and learning: he maintains, that the diſperſion, as well as the confuſion of tongues, was local, and limited to the inhabitants of the province of Babel; that the ſeparation and diſtribution, recorded to have taken place in the days of Peleg, Gen. x. 25, 31, 32. which was the reſult of divine appointment, occaſioned a general migration; and that all the families among the ſons of men were concerned in it: the houſe of Shem, from which the Meſſiah was to ſpring, was particularly regarded in this diſtribution; the portion of his children was near the place of ſeparation; they in general had Aſia to their lot; as Japhet had Europe, and Ham the large continent of Africa. But the ſons of Chus would not ſubmit to the divine diſpenſation; they went off under the conduct of Nimrod, and ſeem to have been for a long time in a roving ſtate: however, at laſt they arrived at the plains of Shinar, and having ejected Aſhur and his ſons, who were placed there by divine appointment, ſeized his dominions, and laid there the foundation of a great monarchy. But afterwards fearing leſt they ſhould be divided and ſcattered abroad, they built the tower of Babel, as a land mark, to which they might repair, and probably to anſwer the purpoſes of an idolatrous temple, or high altar, dedicated to the hoſt of heaven, from which they were never long to be abſent. They only, *viz.* the ſons of Chus or the Cuthites, and their aſſociates from other families, who had been guilty of rebellion againſt divine authority, and of wicked ambition and tyranny, were puniſhed with the judgment of confounded ſpeech through a failure in labial utterance, and of the diſperſion recorded in Gen. x. 8, 9: in conſequence of which they were ſcattered abroad from this city and tower, without any certain place of deſtination. The Cuthites invaded Egypt or the land of Mizraim, in its infant ſtate, ſeized the whole country, and held it for ſome ages in ſubjection; and they extended likewiſe to the Indies and Ganges, and ſtill farther into China and Japan. From them the province of Cuſhan or Goſhen in Egypt derived its name; here they obtained the appellation of royal ſhepherds; and when they were by force driven out of the country, after having been in poſſeſſion of it for two hundred and ſixty, or two hundred and eighty years, the land which they had been obliged to quit was given to the Iſraelites, who were alſo denominated ſhepherds, but ſhould not be confounded with the former or the antecedent inhabitants of Goſhen. Bryant's Analyſis of Ancient Mythol. vol. iii. p. 16, &c. See Cush.

Dispersion *of inflammations*, in *Medicine*. See Inflammations.

DISPLANT-

DISPLANTING, among *Gardeners*, is the plucking up of a tree or plant out of the ground.

DISPLANTING *ſcoop*, an inſtrument for taking up plants, with earth about their roots.

DISPLAYED, in *Heraldry*, is underſtood of the poſition of an eagle, or other bird, when it is erect, with its wings expanded, or ſpread forth.

DISPONDEE, in the *Greek* and *Latin Poetry*, a double ſpondee; or a foot conſiſting of four long ſyllables: as *jūrāmēntūm*, *dēlēctāntē*, θαυμαζονσῶν.

DISPONTIUM, in *Ancient Geography*, a deſerted town of Triphylia, N. of Heraclon, whoſe inhabitants, in the time of Strabo, had emigrated to Epidamnus and Apollinia, a town of Illyria.

DISPOSITION, from *dis*, and *pono*, I place, in *Architecture*, is the juſt placing of all the ſeveral parts of an edifice, according to their proper nature and office. See BUILDING.

DISPOSITION, in *Logic*, is that operation of the mind, whereby we put the ideas, propoſitions, and arguments which we have formed concerning one ſubject, into ſuch an order as is fitteſt to gain the cleareſt knowledge of it, to retain it longeſt, and to explain it to others in the beſt manner: the effect of this is called method. Watt's Logic.

DISPOSITION, in a *Military Senſe*, is the arrangement of an army or body of men upon the moſt advantageous ground, and in the beſt ſituation for a vigorous attack or defence.

DISPOSITION, in *Phyſiology*, denotes a ſtate of mind diſtinguiſhing one man from another and inherent in the conſtitution of nature, which, while it laſts, gives a tendency, or proneneſs, to be moved by certain animal principles, rather than by others; while, at another time, another ſtate of mind, in the ſame perſon, may give the aſcendant to other animal principles. As far as we can trace the cauſes of the different diſpoſitions of the mind, they ſeem to be in ſome caſes owing to thoſe aſſociating powers of the principles of action, which have a natural affinity, and are prone to accompany one another; ſometimes to accidents of good or bad fortune, and ſometimes the ſtate of the body may have an influence on the diſpoſition of the mind. At one time the ſtate of the mind, like a ſerene unclouded ſky, ſhews every thing in the moſt agreeable light; then a man is prone to benevolence, compaſſion, and every kind affection; unſuſpicious, not eaſily provoked. The poets have obſerved, that men have their "mollia tempora fandi," when they are averſe from ſaying or doing a harſh thing, and artful men watch theſe occaſions, and know how to improve them to promote their ends. This diſpoſition is commonly called "good humour," of which, in the fair ſex, Mr. Pope ſays,

> "Good humour only teaches charms to laſt,
> Still makes new conqueſts, and maintains the paſt."

There is no diſpoſition more comfortable to the perſon himſelf, or more agreeable to others than good humour. It is to the mind what good health is to the body; gives a man the capacity of enjoying every thing that is agreeable in life, and of uſing every faculty without impediment. It diſpoſes to contentment, benevolence, and ſympathy; and whilſt it preſents every object in the moſt favourable light, it inclines us to avoid giving or taking offence. This happy diſpoſition ſeems to be the natural fruit of a good conſcience, and of a firm belief that the world is under a wiſe and benevolent adminiſtration; and when it ſprings from this root, it is an habitual ſentiment of piety. The oppoſite diſpoſition, called "bad humour," has a contrary influence; an influence as malignant as the other is ſalutary. It tinges every object with its own diſmal colour, and like a part that is galled, it is hurt by every thing that touches it. It takes offence where none was intended, and diſpoſes to diſcontent, jealouſy, envy, and, in general, to malevolence.

There are other oppoſite diſpoſitions, which are "elation" of mind, on one hand, and "depreſſion" on the other. Theſe may be good or bad, as they are grounded on true or falſe opinion, and as they are regulated. The former, when it ariſes from a juſt ſenſe of the dignity of our nature, is true magnanimity, and diſpoſes a man to the nobleſt virtues, and the moſt heroic actions and enterpriſes. When it ariſes from a conſciouſneſs of our worth and integrity, it may be called the pride of virtue, which is noble and excellent, and conſtitutes the true ſenſe of honour; but when it ſprings from a vain opinion of our poſſeſſing talents or worth, which do not belong to us, or from an undue eſtimate of the value of thoſe we actually poſſeſs, it is pride, and produces arrogance, contempt of others, ſelf-partiality, and vicious ſelf-love. Depreſſion, on the other hand, proceeding from a juſt ſenſe of the weakneſs and imperfections of human nature, and of our own perſonal defects and faults, is true humility, which is not inconſiſtent with real magnanimity. But in, other caſes, it is oppoſite to magnanimity, and debilitates the ſprings of action, and chills every ſentiment that ſhould lead to any noble exertion, or enterpriſe. This depreſſion of mind may ſometimes be owing to melancholy, and may produce ſtrange opinions; and at other times our opinions may have a very conſiderable influence, either to elevate, or depreſs the mind, even where no melancholy attends them. (Reid's Eſſays on the Active Powers of Man, Eſſ. iii. ch. 7.) The diſpoſition, or original bent of the mind, which tends to form, or upon which is grafted, the habitual temper and diſcriminating character, is ſometimes called *propenſity*, which, uſed more generally, includes *principle*, as well as *diſpoſition*.

DISPOSITION, in *Rhetoric*, is defined, by Cicero, the act of diſtributing the things, or arguments, invented, or found out, into a proper order; or, a due placing, or ranging the ſeveral parts of ſpeech, or diſcourſe.

Diſpoſition in oratory differs from that operation of the mind which is ſo called by logicians. The logician ſo places the ſeveral propoſitions of a ſyllogiſm in a certain preſcribed method, that the relation between the terms may be evident, and the concluſion appear to be fairly drawn from the premiſes. And if either of the premiſes ſeems weak, or the truth of it not ſufficiently clear, he ſupports it by a freſh argument; and ſo proceeds in one ſuccinct and uniform chain of reaſoning, till he has made out the proof of what he had at firſt propoſed. But the orator is not thus tied down to mode and figure; or to perfect ſyllogiſms, which he ſeldom uſes: but reaſons in the manner that ſeems to him moſt convenient: he begins with either of the premiſes, and ſometimes with the concluſion itſelf; confirms one part with proper reaſons, and enlarges upon it for greater evidence and variety, before he proceeds to another; and drops any part, which he thinks ſufficiently clear of itſelf, and may be ſupplied by the attentive hearer. And thus, by a diverſity of method, and an agreeable variety, he conſults the pleaſure and entertainment of his hearers, as well as their inſtruction. Beſides, he conſiders the frame and ſtructure of his whole diſcourſe, and as his view is not every where the ſame, he divides it into certain parts, and ſo diſpoſes each of them, as may beſt anſwer his intention. From all which it appears, that diſpoſition, conſidered as a part of oratory, is widely different from that which logic teaches.

Diſpoſition

Diſpoſition makes one of the great branches, or diviſions, of rhetoric. Iſocrates was the firſt among the Greeks, that made them ſenſible of the beauty of diſpoſition; and Cicero among the Romans.

The diſpoſition is of the ſame neceſſity in oratory, as the marſhalling of an army in order to a battle; or a beautiful compoſition in architecture, painting, &c. Horace enjoins it expreſsly in poetry: "Singula quæque locum teneant ſortita decenter." Quintilian has well obſerved, (Inſt. Orat. lib. vii.); "A diſcourſe that wants diſpoſition muſt neceſſarily be confuſed, and without connection, liable to frequent tautologies and omiſſions; and like one wandering in the dark, be conducted by chance rather than deſign." Order and regularity are always pleaſant and agreeable; we admire them in nature; and they are no leſs beautiful in art, and particularly in diſcourſe. The diſpoſition, then, is the order, or arrangement, of the parts of an oration; which parts are uſually reckoned four, *viz.* the exordium, or introduction; the narration; the confirmation; and the peroration, or concluſion. Ariſtotle, (De Rhetor. l. iii. c. 13.) mentions the four following; *viz.* introduction, propoſition, proof, and concluſion. Quintilian, (Inſt. Orat. l. iii. c. 9.) makes five parts, introduction, narration, confirmation, refutation, and concluſion. Though ſome make them ſix, *viz.* the exordium, diviſion, narration, confirmation, confutation, and peroration; as indicated in that popular verſe:

"Exorſus, narro, ſeco, firmo, refuto, peroro."

But the diviſion is more naturally referred to the exordium; and the confutation to the confirmation. Cicero alſo, (De Invent. l. i. c. 14.) enlarges them to ſix, thus: introduction, narration, propoſition, confirmation, confutation, and concluſion.

The diſpoſition is either natural, or artificial. Natural, is the order the parts are above rehearſed in. Artificial, is when, for ſome particular reaſon, we recede from the order of nature. See each part under its proper article, Exordium, &c.

DISPOSSESSION, in *Law*. See Disseisin and Ouster.

DISPROPORTION, a term of relation implying a want of proportion, or ſymmetry.

DISPROVING, in *Rhetoric*. See Refutation.

DISPUTE, or Disputation, from *dis*, and *puto*, I think, in the *Schools*, *&c.* a conteſt, or combat, either by word, or writing, on ſome point of learning, or religion, for a degree, prize, exerciſe, or even for the mere ſake of truth, or advantage of a party, or the honour of a triumph. See Thesis.

The Port Royaliſts take occaſion to obſerve, that nothing gives ſo many different lights and openings, for diſcovering the truth, as diſputation. The movements of a mind, employed ſingly in the examination of any ſubject, are uſually too cool and languid; the mind needs a certain degree of heat to awake its ideas. Now, by the oppoſitions in a diſpute, we come to find wherein the difficulty lies, and the vigour the mind has acquired enables us to ſurmount it.

DISQUISITION, from *dis*, and *quæro*, I enquire, an enquiry into the nature, kinds, and circumſtances of any problem, queſtion, or topic; in order to gain a right notion of it, and to diſcourſe clearly about it.

DISS, in *Geography*, a market town and pariſh, in the hundred of Diſs. in the county of Norfolk, England, is 14 miles ſouth of Norwich, and 90 from London. It is built on the northern bank of the river Waveney, which divides the counties of Norfolk and Suffolk at this place, and contains 325 houſes, with 2246 inhabitants. The principal ſtreets are paved, and many of the houſes are well built, preſenting an aſpect of comfort and reſpectability. Here are ſome manufactories for hempen cloth and hoſe; and many of the inhabitants are employed in making ſtays. The markets, held on Fridays, are ſupplied with great quantities of yarn, linen cloth, and proviſions. The church is a large ancient building. John Skelton, king's orator and poet-laureat to Henry VIII., was rector of this town for many years. Blomefield's Hiſtory of Norfolk.

DISSAY, a ſmall town of France, in the department of the Vienne; nine miles S. E. of Château du Loir.

DISSDORF, a town of Germany, in the circle of Upper Saxony, and Old Mark of Brandenburg; 16 miles W. S. W. of Salzwedel.

DISSECTION, in *Anatomy*, from *dis* and *ſeco*, *I cut*, is the diviſion of any part of the body by means of knives, ſciſſars, &c. This, in general, is performed on the dead ſubject, for the purpoſe of expoſing the different organs in their natural ſituation, and learning their connections and ſtructure. In its moſt extenſive ſenſe, it may be conſidered to include, not merely the ſimple expoſure and diviſion of the parts in a recent body, but alſo every proceſs in practical anatomy which can contribute to elucidate the ſtructure of our frame; as all the methods of preparing the various organs, by means of injection, maceration, corroſion, &c.; of preſerving theſe by drying, varniſhing, immerſion in ſpirits, oil of turpentine, and other liquors, which conſtitute the art of making anatomical *preparations*. This branch of diſſection is exerciſed with a view to diſcover the natural ſtructure and relations of parts; but we employ it alſo, in order to obſerve the effects produced in the organization of the body by diſeaſe, and this conſtitutes *morbid* anatomy. Every proceſs then that can tend to illuſtrate the ſtructure of the body, whether in health or diſeaſe, and to expoſe its component parts in their natural or morbidly changed relations of figure, poſition, and connection, may be regarded as a branch of the art of diſſection. This is the way in which we propoſe to conſider the ſubject in the preſent work; but as, in this mode of regarding it, diſſection becomes moſt intimately connected with the art of making anatomical preparations, we ſhall refer the whole account to that article.

Dissection *of Murderers*. See Murder.

DISSEISIN, in *Law*, an unlawful diſpoſſeſſing a man of his land, tenement, or other immoveable and incorporeal right.

This is a ſpecies of injury by ouſter, or a privation of the freehold, conſiſting in a wrongful putting out of him that is ſeiſed of the freehold. It differs from *abatement* and *intruſion*, which denote a wrongful entry where the poſſeſſion was vacant, by its being an attack upon him who is in actual poſſeſſion, and turning him out of it. The former were an ouſter from a freehold in law, this is an ouſter from a freehold in deed. Diſſeiſin may be effected either in corporeal inheritances, or incorporeal. Diſſeiſin of things corporeal, as of honſes, lands, &c. muſt be by entry and actual diſpoſſeſſion of the freehold (Co. Litt. 181.); as if a man enters either by force or fraud into the houſe of another, and turns, or at leaſt keeps, him or his ſervants out of poſſeſſion. Diſſeiſin of incorporeal hereditaments cannot be an actual diſpoſſeſſion; for the ſubject itſelf is neither capable of actual bodily poſſeſſion, nor diſpoſſeſſion; but it depends on their reſpective natures and various kinds; being, in general, nothing more than a diſturbance of the owner in the means of coming at, or enjoying them. With regard to freehold rent in particular, our ancient law-books (Finch. L. 165, 166. Litt. § 237, &c.) mention five methods of working a diſſeiſin

diſſeiſin thereof: 1. By *encloſure;* where the tenant ſo encloſeth the houſe or land, that the lord cannot come to diſtrain thereon, or demand it: 2. By *foreſtaller*, or lying in wait; when the tenant beſetteth the way with force and arms, or by menaces of bodily hurt, affrights the leſſor from coming: 3. By *reſcous;* that is, either by violently retaking a diſtreſs taken, or by preventing the lord, with force and arms, from taking any at all: 4. By *replevin;* when the tenant replevies the diſtreſs at ſuch time when his rent is really due: 5. By *denial;* which is, when the rent being lawfully demanded is not paid. All, or any of theſe circumſtances, amount to a diſſeiſin of rent; that is, they wrongfully put the owner out of the only poſſeſſion, of which the ſubject matter is capable, namely, the receit of it. But all theſe diſſeiſins of hereditaments incorporeal, are only ſo at the election and choice of the party injured; if, for the ſake of more eaſily trying the right, he is pleaſed to ſuppoſe himſelf diſſeiſed (Litt. § 588, 589.) Otherwiſe, as there can be no actual diſpoſſeſſion, he cannot be compulſively diſſeiſed of any incorporeal hereditament. Thus alſo, even in corporeal hereditaments, a man may frequently ſuppoſe himſelf to be diſſeiſed, when he is not ſo in fact, for the ſake of entitling himſelf to the more eaſy and commodious remedy of an ASSISE *of novel diſſeiſin*, (which ſee,) inſtead of being driven to the more tedious proceſs of a writ of entry (4 Burr. 110.). The true injury of compulſive diſſeiſin, ſeems to be that of diſpoſſeſſing the tenant, and ſubſtituting oneſelf to be the tenant of the land in his ſtead; in order to which, in the times of pure feodal tenure, the conſent or connivance of the lord, who, upon every deſcent or alienation, perſonally gave, and who, therefore, alone could change the ſeiſin or inveſtiture, ſeems to have been conſidered as neceſſary. But when, in proceſs of time, the feodal form of alienations were off, and the lord was no longer the inſtrument of giving actual ſeiſin, it is probable that the lord's acceptance of rent or ſervice, from him who had diſpoſſeſſed another, might conſtitute a complete diſſeiſin. Afterwards, no regard was had to the lord's concurrence, but the diſpoſſeſſor himſelf was conſidered as the ſole diſſeiſor; and this wrong was then allowed to be remedied by entry only, without any form of law, or againſt the diſſeiſor himſelf; but required a legal proceſs againſt his heir or alienee. And when the remedy by aſſiſe was introduced, under Henry II., to redreſs ſuch diſſeiſins as had been committed within a few years next preceding, the facility of that remedy induced others, who were wrongfully kept out of the freehold, to feign, or allow themſelves to be diſſeiſed, merely for the ſake of the remedy. Blackſt. Comm. book iii. ch. 10.

By Magna Charta, 9 Henry III. c. 29, no man is to be diſſeiſed, or put out of his freehold, but by lawful judgment of his peers, or by the law of the land; and by ſtat. 32 Hen. VIII. c. 33. the dying ſeiſed of any diſſeiſor of, or in any lands, &c. having no right therein, ſhall not be a deſcent in law, to take away an entry of a perſon having lawful title of entry, except the diſſeiſor hath had peaceable poſſeſſion five years, without entry or claim by the perſon having lawful title. See DISSEISOR.

Diſſeiſin, according to ſome writers, is of three ſorts, *viz.* ſimple diſſeiſin, committed by day, without force and arms: and diſſeiſin by force, for which ſee DEFORCEOR, and FRESH *diſſeiſin*. See alſo RE-DISSEISIN and POST-DISSEISIN.

Aſſiſes are called writs of diſſeiſin, which lie againſt diſſeiſors in any caſe: whereof ſome are termed little writs of diſſeiſin, as being vicontial, that is, ſuable before the ſheriff in the county-court, becauſe determinable by him without aſſize.

DISSEISIN, *aſſiſe of novel*. See ASSISE.

DISSEISIN, *warranty by*. See WARRANTY.

DISSEISOR, he who diſſeiſeth, or puts another out of his land: as *diſſeiſee* is he who is put out.

If a diſſeiſor, after he has expelled the right owner, gains peaceable poſſeſſion of the lands five years without claim, and continues in poſſeſſion, ſo as to die ſeiſed, and the land deſcends to his heirs, they will have a right to the poſſeſſion till the owner recovers at law; and the owner ſhall loſe his eſtate for ever, if he doth not proſecute his ſuit within the time limited by the ſtatute of limitations.

And if a diſſeiſor levy a fine of the land whereof he is diſſeiſed unto a ſtranger, the diſſeiſor ſhall keep the land for ever; for the diſſeiſor againſt his own fine cannot claim, and the conuſee cannot enter, and the right which the diſſeiſor had, being extinct by the fine, the diſſeiſor ſhall take advantage of it. (2 Rep. 56.) But this is to be underſtood, where no uſe is declared of the fine by the diſſeiſee; when it ſhall enure to the uſe of the diſſeiſor, &c. (1 Lev. 128.) See CLAIM, *continual*. A diſſeiſor in aſſize, where damages are recovered againſt him, ſhall recover as much as he hath paid in rents chargeable on the lands before the diſſeiſin. (Jenk. Cent. 189.) But if the diſſeiſor or his feoffee ſows corn on the land, the diſſeiſee may take it before or after ſeverance. (Dyer 31. 173. 11 Rep. 46.) Where a man hath a houſe in fee, &c. and locks it, and then departs; if another perſon comes to his houſe, and takes the key of the door, and ſays that he claims the houſe to himſelf in fee, without any entry into the houſe, this is a diſſeiſin of the houſe. (2 Danv. Abr. 624.) If the feoffor enters on the land of the feoffee, and makes a leaſe for years, &c. it is a diſſeiſin; though the intent of the parties to the feoffment was, that the feoffee ſhould make a leaſe to the feoffor for life. (2 Rep. 59.) If leſſee for years is ouſted by his leſſor, this is ſaid to be no diſſeiſin. (Cro. Jac. 678.) A man who enters on another's land, claiming a leaſe for years, who hath not ſuch leaſe, is a diſſeiſor; though if a man enters into the houſe of another by his ſufferance, without claiming any thing, it will not be a diſſeiſin. (9 Hen. VI. 21, 31. 2 Danv. 625.) If a perſon enters on lands by virtue of a grant or leaſe, that is, void in law, he is a diſſeiſor. (2 Danv. 630.)

As the king in judgment of law can do no wrong, he cannot be a diſſeiſor. (1 Ed. V. 8.) A diſſeiſor is to be fined and impriſoned; and the diſſeiſee reſtored to the land, &c. by ſtat. 20. Hen. III. c. 3. Where a diſſeiſor is diſſeiſed, it is called diſſeiſin upon diſſeiſin.

DISSEMINATE VACUUM. See VACUUM *diſſeminatum*.

DISSEN, in *Geography*, a ſmall town of Germany, in the circle of Weſtphalia, which formerly belonged to the biſhopric of Oſnabruck, but is at preſent included in the poſſeſſions of the new king of Weſtphalia.

DISSENHOFEN. See DIESSENHOFEN.

DISSENTERS, a general denomination of equal import with non-conformiſts; and comprehending certain ſects, or parties, in England, who, in matters of religion, church diſcipline, and ceremonies, diſſent from, or diſagree with the church of England, and have a toleration by law for the ſame Such, particularly, are the preſbyterians, independents, anabaptiſts, and quakers. See PRESBYTERIANS, &c.

The diſſenters, with reſpect to their legal condition, have, in former periods, been ſubject to ſeveral diſabilities and reſtrictions, (which, ſays judge Blackſtone, I ſhall not undertake to juſtify,) laid upon them by abundance of ſtatutes (23 Eliz. c. 1. 29 Eliz. c. 6. 35 Eliz. c. 1. 22 Car. II. c. 1.); concerning which he obſerves, "that the legiſlature, with a ſpirit of true magnanimity, extended that indulgence to theſe ſectaries, which they themſelves, when in power, had held

held to be countenancing ſchiſm, and denied to the church of England;" (referring to the ordinance of 1645, which enforced the uſe of the DIRECTORY, and which inflicted impriſonment for a year on the third offence, and pecuniary penalties on the former two, in caſe of uſing the book of common prayer, not only in a place of public worſhip, but alſo in any private family.) The penalties are conditionally ſuſpended by the ſtatute 1 W. and M. ſt. 1. c. 18. "for exempting their majeſties' proteſtant ſubjects, diſſenting from the church of England, from the penalties of certain laws," commonly called the TOLERATION *act* (which ſee); which act is confirmed by ſtatute 10 Ann. c. 2. and declares, that neither the laws above-mentioned, nor the ſtatutes 1 Eliz. c. 2. § 14. 3 Jac. I. c. 4 and 5, nor any other penal laws made againſt popiſh recuſants (except the teſt acts) ſhall extend to any diſſenters, other than papiſts and ſuch as deny the Trinity: provided, 1. That they take the oaths of allegiance and ſupremacy (or make a ſimilar affirmation, being quakers, ſtat. 8 Geo. I. c. 6) and ſubſcribe the declaration againſt popery; 2 That they repair to ſome congregation certified to and regiſtered in the court of the biſhop or archdeacon, or at the county ſeſſions; 3. That the doors of ſuch meeting-houſe ſhall be unlocked, unbarred, and unbolted, in default of which the perſons meeting there are ſtill liable to all the penalties of the former acts. Diſſenting teachers, in order to be exempted from the penalties of the ſtatutes 13 and 14 Car. II. c. 4. 15 Car. II. c. 6. 17 Car II. c. 2. and 22 Car. II. c. 1. are alſo to ſubſcribe the articles of religion mentioned in the ſtatute 13 Eliz. c. 12. (which only concerns the confeſſion of the true Chriſtian faith and the doctrine of the ſacraments,) with an expreſs exception of thoſe relating to the government and powers of the church, and to infant baptiſm: or if they ſcruple ſubſcribing the ſame, ſhall make and ſubſcribe the declaration preſcribed by ſtatute 19 Geo. III. c. 44. profeſſing themſelves to be Chriſtians and proteſtants, and that they believe the ſcriptures to contain the revealed will of God, and to be the rule of doctrine and practice. Thus, though the *crime* of non-conformity, as Blackſtone expreſſes it, is by no means univerſally abrogated, it is ſuſpended and ceaſes to exiſt with regard to thoſe proteſtant diſſenters, during their compliance with the conditions impoſed by theſe acts; and, under theſe conditions, all perſons who will approve themſelves no papiſts or oppugners of the Trinity, are left at full liberty to act as their conſciences ſhall direct them, in the matter of religious worſhip. And if any perſon ſhall wilfully, maliciouſly, or contemptuouſly diſturb any congregation, aſſembled in any church or permitted meeting-houſe, or ſhall miſuſe any preacher or teacher there, he ſhall (by virtue of the ſame ſtatute 1 W. and M.) be bound over to the ſeſſions of the peace, and forfeit 20*l*. But by ſtatute 5 Geo. I. c. 4. no mayor or principal magiſtrate muſt appear at any diſſenting meeting with the enſigns of his office, on pain of diſability to hold that or any other office: the legiſlature judging it a matter of propriety, that a mode of worſhip ſet up in *oppoſition* to the national (ſays the learned judge) when allowed to be exerciſed in peace, ſhould be exerciſed alſo with decency, gratitude, and humility.

Diſſenters alſo, who ſubſcribe the declaration of the act 19 Geo. III. are exempted (unleſs in the caſe of endowed ſchools and colleges) from the penalties of the ſtatutes 13 and 14 Car. II. c. 4. and 17 Car. II. c. 2. which prohibit (upon pain of fine and impriſonment) all perſons from teaching ſchool unleſs they be licenſed by the ordinary, and ſubſcribe a declaration of conformity to the liturgy of the church, and reverently frequent divine ſervice *eſtabliſhed* by the laws of this kingdom.

Diſſenters choſen to any parochial or ward offices, and ſcrupling to take the oaths, may execute the office by deputy, who ſhall comply with the law in this behalf. (Stat. 1 W. & M. ſt. 1. c 18.) See CONSTABLE. Diſſenters are not ſubject to fine on refuſing to ſerve corporation offices. For where a freeman of London was elected one of the ſheriffs, but refuſed to take the office on account of his being a diſſenter, and as ſuch not having received the ſacrament according to the rites of the church of England, within a year before his election, an action was brought againſt him in the ſheriff's court for the penalty incurred by ſuch refuſal, and a judgment recovered, which judgment was affirmed in a writ of error brought in the court of Huſtings. But the defendant having obtained a ſpecial commiſſion of errors, the judges delegates reverſed both judgments; and on a writ of error in parliament, this judgment of reverſal was affirmed; the judges (except one) being of opinion that the defendant was at liberty to object to the *validity* of his election on the ground of his own non conformity. (3 Bro. P. C 8vo. ed. 465. Harriſon v. Evans.) The general principle and ſpirit of this deciſion, reſtricted in this caſe to the ſheriffs of corporations, have been thought to extend to thoſe of counties; and in ſeveral caſes that have ſince occurred the obligation of ſerving this office, under the plea of diſſent, has not been enforced.

The diſſenters have complained that judge Blackſtone has not truly repreſented their preſent legal condition. According to his ſtatement mere non-conformity is a crime, though, as he elſewhere ſays, not ſo great as ſome others, and is ſo conſidered in the eye of the law, notwithſtanding the toleration-act The *penalties*, indeed, by that act, are *ſuſpended*, but the *crime* ſtill ſubſiſts. Upon this ſtatement it has been obſerved by an able advocate of their cauſe (ſee letters to Blackſtone by P. Furneaux, D. D. 1770), that ſuſpenſion of penalty is not the language of the toleration-act. The act uſes a comprehenſive and forcible expreſſion, which excludes the *crime* as well as the *penalty*; it leaves theſe penal ſtatutes no operation at all, with reſpect to the diſſenters who are under the toleration act; it repeals and annihilates thoſe ſtatutes with regard to ſuch diſſenters. The words of the act are, that thoſe ſtatutes ſhall not be conſtrued to *extend* to ſuch perſons; and if they are not to be conſtrued to *extend* to them, nothing can be plainer, than that they are not to be conſtrued to *affect them at all*, either as to crime or penalty. If, therefore, the ſtatute-law doth not make non-conformity a crime, it is certain that it is no crime at all by the common law; becauſe the conſtitution of the church, and its peculiar doctrine, worſhip, diſcipline, and government are founded wholly upon the ſtatute-law, and not at all upon the common law. It would have been more juſt, as well as more candid, if the learned judge had ſaid, that all penal laws for non-conformity are *repealed*, with regard to thoſe diſſenters who are qualified as the act directs. It has been farther alleged, that both the crime and penalty of mere proteſtant non-conformity to the eſtabliſhed rites and modes of worſhip appear to be aboliſhed, by the act of toleration, from the protecting clauſes of that act; which, in the words of a great lawyer, (the late lord Mansfield.) have rendered the diſſenters' way of worſhip "not only innocent but lawful; have put it, not merely under the connivance, but under the protection of the law; have *eſtabliſhed* it. For nothing can be plainer than that the law protects nothing in that very reſpect, in which it is, at the ſame time, in the eye of the law a crime. Diſſenters, by the act of toleration, therefore, are reſtored to a legal conſideration and capacity." Beſides, the unanimous judgment of the commiſſioners-delegates, and of the houſe of lords affirming that judgment (Feb. 7, 1767), in the great cauſe between

between the city of London and the diſſenters, concerning the fine inflicted by a bye-law of the city on thoſe who refuſed the office of ſheriff, was grounded entirely on this opinion, *viz.* "that the toleration act removed the crime as well as the penalty of mere non-conformity." The arguments of the judges in this cauſe turned upon the ſingle point, "that the toleration act removed the *crime* as well as the *penalties* of non-conformity;" and in this they all, except one, agreed. The whole was ſummed up and the reaſoning on the oppoſite ſide examined and confuted, with great perſpicuity and force of argument, by lord Mansfield; and upon this ground the houſe of lords affirmed, *nemine contradicente*, the judgment of the commiſſioners delegates. Mr. Onſlow, formerly ſpeaker of the houſe of commons, whoſe excellent principles and character have been always held in high eſtimation, declared his decided approbation of the term *eſtabliſhed*, as applied by the noble lord already mentioned to the worſhip of diſſenters, and he moreover ſaid that this was the language which he himſelf always uſed; adding, that as far as the authority of the law could go in point of *protection*, the diſſenters were as *truly eſtabliſhed* as the church of England; and that an eſtabliſhed church, as diſtinguiſhed from their places of worſhip was, properly ſpeaking, an *endowed church*; a church which the law not only protected, but endowed with temporalities for its peculiar ſupport and encouragement. It deſerves to be conſidered, that the penalties inflicted by the act of toleration on thoſe who diſturb any diſſenting congregation for divine worſhip, or miſuſe the preacher, are preciſely the ſame as on thoſe who diſturb the congregation, or miſuſe the preacher in any cathedral, pariſh church, or chapel; and diſſenting miniſters, as well as the clergy of the church of England, are excuſed from all burdenſome offices.

Having ſtated the law, as it now exiſts with regard to diſſenters, we ſhall here introduce, for the ſatisfaction of our readers, a brief account of their principles and conduct. This ſeems to be the more neceſſary in a work that profeſſes to do juſtice to perſons of every party and profeſſion, both civil and religious, becauſe ſome for want of due information (as it is imagined) have conceived them to be a body of perverſe and obſtinate people, who ſeparate from the eſtabliſhed church without ſufficient reaſon; and others, for want of adverting to their diſcriminating character and general conduct, repreſent them as enemies to the conſtitution and government of their country. A juſt and candid ſtatement of their diſtinguiſhing tenets is ſuch as they have a right to expect: and it will ſerve, as the writer of this article apprehends, to conciliate different parties of Chriſtian profeſſors, to produce mutual forbearance and concord, and thus uniting the ſeveral members of the community by candour, charity, and good-will, to promote the permanence and proſperity of a country, to the honour and welfare of which they are zealouſly attached. The diſſenters have complained (how far they have had juſt grounds for complaint we leave others to judge) that their principles and character have been miſunderſtood and miſrepreſented: but at the tribunal of this enlightened age they can have nothing to fear, as their cauſe will be liberally tried and determined. Judge Blackſtone ſpeaks of them as "a ſpecies of non-conformiſts, who offend through a miſtaken or perverſe zeal. Such (he ſays) were eſteemed by our laws, enacted ſince the time of the reformation, to be papiſts and proteſtant diſſenters: both of which were ſuppoſed to be equally ſchiſmatics in not communicating with the national church; with this difference, that the papiſts divided from it upon material, though erroneous, reaſons: but many of the diſſenters upon matters of indifference, or, in other words, upon no reaſon at all." He allows, however, that our anceſtors were miſtaken in their plans of compulſion and intolerance; and that all perſecution for diverſity of opinions, however ridiculous or abſurd they may be, is contrary to every principle of ſound policy and civil freedom. The names and ſubordination of the clergy, the poſture of devotion, the materials and colour of the miniſter's garment, the joining in a known or unknown form of prayer, and other matters of the ſame kind, muſt be left to the option of every man's private judgment. Nevertheleſs, he reflects on the conduct of thoſe puritans, from whom they derive their pedigree, who concurred in the ordinance of 1645, which they alſo condemn (ſee DIRECTORY); without adverting to the period in which they lived, to the exaſperated feelings which they might poſſibly have unduly indulged, and without allowing for the imperfect and miſtaken ſentiments concerning toleration, which then too generally prevailed. He ſeems alſo to forget, as the diſſenters would argue, the ſevere ſufferings which the puritans experienced both before and after the period to which he refers, and which cannot be parallelled by any event that occurred during the interval of the interregnum. The diſſenter would contraſt (if recrimination were allowed) againſt the unwarrantable conduct of the parliament in 1645, the unrelenting rigours of archbiſhops Parker, Bancroft, Whitgift, and Laud. Under the firſt of theſe, he would ſay, more than 100, and under the ſecond, more than 300, pious and learned men, not only members, but miniſters of the eſtabliſhed church, were ſilenced, ſuſpended, admoniſhed, deprived; many of them loaded with grievous and heavy fines, and ſhut up in noiſome gaols, where they expired ſlowly through penury and diſeaſe: and he would ſay, the crimes for which they ſuffered theſe ſevere puniſhments were merely their ſcruples about the ſurplice and the cap, about bowing at the name of Jeſus, about Chriſt's deſcent into hell, and ſimilar momentous points. The diſſenter would call to mind the hundreds that were ſequeſtered, driven from their livings, proſecuted in the high commiſſion court, and forced to leave the kingdom for not punctually conforming to all the ceremonies and rites deviſed or enforced by Laud, and for not daring to tell their people, that they might lawfully profane the ſabbath-day by gambols and ſports. He would, moreover, allege, that many of the canons breathe a perſecuting ſpirit, and that the act of uniformity was an unrighteous and perſecuting act; by the operation of which more than 2000 excellent and pious miniſters were excluded from the church, and abandoned, with their ſtarving families, to great poverty and diſtreſs. This diſtreſs, it might be urged, was aggravated by another act, which baniſhed them five miles from any city, borough, or church in which they had before officiated, and which removed them to a diſtance from their acquaintance and friends, who might have miniſtered to their relief. The diſſenter, in pleading his own cauſe, would mention another act, which forbade their meeting to worſhip God any where but in the eſtabliſhed churches, under the penalties of heavy fines, impriſonment, and baniſhment to foreign lands. In conſequence of theſe cruel acts, it is ſaid, that great numbers of pious clergymen, with multitudes of their people, were laid in priſons amongſt thieves and common malefactors, where they ſuffered the greateſt hardſhips, indignities, and oppreſſions; their houſes were rudely rifled, their goods made a prey to hungry informers, and their families given up to beggary and want. An eſtimate is ſaid to have been publiſhed of near 8000 proteſtant diſſenters, who had periſhed in priſon in the reign only of Charles II. By ſevere penalties inflicted on them for aſſembling to worſhip God, they ſuffered in their trade and eſtates, in the compaſs of a few

years, at leaſt two millions; and a liſt of 60,000 perſons was taken, who had ſuffered on a religious account, betwixt the reſtoration and the revolution. (See Neal's Hiſt. Purit. vol. ii. p. 759.) The diſſenters have alſo complained of the diſabilities and diſgrace entailed upon them by the *Corporation* and *Teſt* acts; and alſo of the temporary injury which they ſuffered from the *Schiſm* and *Occaſional Conformity* acts.

Diſſenters, in the moſt general ſenſe of the term, as comprehending thoſe who diſapproved the doctrines and forms of worſhip ſanctioned by the authority of the eſtabliſhed church, have exiſted in this country for many ages. According to this latitude of the appellation, the famous John Wickliffe, who lived in the 14th century, was a diſſenter: for, independently of his objections to ſeveral doctrines of the church of Rome, then the eſtabliſhed church of England, he maintained moſt of thoſe points by which the puritans were afterwards diſtinguiſhed. But it was not till after the reformation, in the year 1548, and under the reign of king Edward VI., that the controverſy commenced, which afterwards occaſioned a ſeparation from the church. This controverſy aroſe from biſhop Hooper's refuſing to be conſecrated in the popiſh habits. This circumſtance produced a diviſion among the reformers, and gave riſe to the two parties of "Conformiſts" and "Non-conformiſts;" archbiſhop Cranmer and Ridley being at the head of the former, and biſhop Hooper, Rogers, and the foreign divines, eſpouſing and ſupporting the cauſe of the latter. Under the reign of queen Mary, when popery was re-eſtabliſhed, many of the more eminent reformers fled abroad for ſecurity; and at Franckfort, where the number of exiles was moſt conſiderable, that conteſt and diviſion began, which, in 1556, gave riſe to the puritans, and to that ſeparation from the church of England, which continues to this day. (See Puritans.) Soon after the acceſſion of queen Elizabeth, *viz.* in the year 1559, "An Act for the Uniformity of Common Prayer and Service in the Church, and Adminiſtration of the Sacraments" was paſſed; and upon this fatal rock of uniformity in things merely indifferent, in the opinion of the impoſers, was the peace of the church of England ſplit. The court reformers and the puritans were divided in opinion, with regard to a variety of ſubjects that engaged their attention. The principal queſtion, however, concerning which they diſagreed, related to the obligation and enforcement of things indifferent in their own nature, which, as the reformers maintained, might be ſettled, determined, and made neceſſary by the command of the civil magiſtrate, and authoritatively enjoined on the obſervance of all ſubjects; but, with regard to theſe the puritans inſiſted, that things which Chriſt had left indifferent, ought not to be made neceſſary by any human laws; and that ſuch rites and ceremonies as had been abuſed to idolatry, and manifeſtly tended to lead men back to popery and ſuperſtition, were no longer indifferent, but were to be rejected as unlawful. It is to be regretted, that both parties were too well agreed, in aſſerting the neceſſity of uniformity in public worſhip, and of uſing the ſword of the magiſtrate for the ſupport and defence of their reſpective principles; which they miſemployed in their turns, whenever they could graſp the power into their hands. The ſtandard of uniformity, according to the biſhops, was "the queen's ſupremacy and the laws of the land;" according to the puritans, "the decrees of provincial and national ſynods," allowed and enforced by the civil magiſtrate; but neither party was for admitting that liberty of conſcience, and freedom of profeſſion, which is every man's right, as far as is conſiſtent with the peace of the civil government under which he lives. The terms of miniſterial conformity at this time, *viz.* in 1560, were the oath of ſupremacy, compliance with the act of uniformity, and a declaration of faith, iſſued by order of both archbiſhops, metropolitans, and the reſt of the biſhops, for the unity of doctrine, &c. Many of the learned exiles, who were now returning home, and others, diſapproved of the ſecond article, and refuſed to accept of livings in the church, according to the act of uniformity, and the queen's injunctions. The queſtion about habits was ſoon after revived; and the diſcuſſion of it produced conſiderable agitation. Thoſe who refuſed them were puniſhed in a variety of ways. At length, *viz.* in 1566, the impoſition of the habits, and ſome other ceremonies, which the puritans were compelled by law to adopt, produced a ſeparation. In the following year, they urged a great number of other objections againſt the hierarchy, and various ceremonies, for the uſe of which there was no foundation in Scripture, or primitive antiquity; and which, therefore, as they argued, ought not to have been impoſed. In points of doctrine there was no difference between the puritans and conformiſts. The chief leaders of the ſeparation were beneficed perſons within the dioceſe of London; and theſe had their followers of the laity, who forſook their pariſh churches, and aſſembled with the deprived miniſters in woods and private houſes, to worſhip God, without the habits and ceremonies of the church. Many ſevere meaſures were adopted, in order to compel them to ſubmit; but they were ineffectual; nor did any efforts for parliamentary relief, on the part of the puritans, prove of any avail. See Puritans.

The reſtoration of Charles II. in 1660, was accompliſhed at a period when the preſbyterians, one claſs of proteſtant diſſenters, were in poſſeſſion of the whole power of England; and they were the principal inſtruments of effecting it. They have been juſtly blamed, however, for bringing in the king without a previous treaty, and for truſting a ſet of men, whom they knew to be their implacable enemies. Many of them lived long enough to ſee their error, and heartily to repent of it. The king was ungrateful; ſoon forgot his promiſes of kindneſs; and in the year 1661, the corporation act was paſſed. (See Corporation.) This was ſoon followed by the Savoy conference, which terminated without ſucceſs, as no alterations were made in the common-prayer book that were favourable to the preſbyterians, for it was reſolved to gratify them in nothing. Indeed, the common-prayer book was made more exceptionable, and the terms of conformity much harder than before the civil war. See Conference.

In the ſpring of 1662, "the act of uniformity" was brought into parliament (ſee Uniformity); and in conſequence of it the terms of conformity were higher than before the civil wars. The preſbyterian miniſters were allowed only three months to conſider what to do with themſelves and their families. Beſides other objections which occurred, that which the diſſenters, of all denominations, refuſed, was giving "their aſſent and conſent to all and every thing contained in the book of common prayer." This, they apprehended, to be more than was due to any human compoſition. Some of the non-conformiſts quitted their ſtations in the church before the 24th of Auguſt; and when the fatal St. Bartholomew came, about 2000 miniſters relinquiſhed their preferments in the church, or refuſed to accept of any on the terms of the act of uniformity. Among theſe were many men much valued and diſtinguiſhed by their abilities and zeal, caſt out of their poſſeſſions in an ignominious manner, deprived of their means of ſubſiſtence and opportunities of uſefulneſs, and reduced to a neceſſity, which both their principles and their circumſtances

ſtances juſtified, of forming ſeparate congregations. The perſecution they thus ſuffered tended to excite compaſſion, and to enſure eſteem.

Mr. Locke calls them worthy, learned, pious, orthodox divines, who did not throw themſelves out of ſervice, but were forciby ejected. So injurious was this event to the church itſelf, that many poor livings in the country had no incumbents for a conſiderable time. Many, who complied with the terms of conformity, did it, not becauſe they approved them, but for the ſake of their families, or becauſe they were unwilling to be buried in ſilence. Several young ſtudents, who were deſigned for the pulpit, applied themſelves to law or phyſic, or diverted their views to ſome ſecular employment. This act was paſſed after the king had engaged his faith and honour in his declaration from Breda, to preſerve liberty of conſcience inviolable; which promiſe opened the way for his reſtoration; and after the royaliſts had given public aſſurance, that all former animoſities ſhould be laid aſide as rubbiſh, under the foundation of univerſal concord.

The name of puritans was now changed into that of proteſtant non-conformiſts; who were ſub-divided into preſbyterians, independents, anabaptiſts, and quakers. The king was a concealed Roman catholic; and the court was diſpoſed to paſs the act of uniformity in the ſevereſt terms, in order to make the number of diſſenters more conſiderable; and when this was objected, it was replied, the more diſſenters the better, becauſe it will make a toleration more needful, in which the papiſts will be included. In December 1662, the king, with the advice of his privy council, publiſhed his declaration of indulgence. This was ſucceeded, on the pretence of a plot in the north, by an act for ſuppreſſing ſeditious conventicles (16 Car. II. c. 4.) (See CONVENTICLE.) In October 1665, the Oxford five-mile act, entitled "An act to reſtrain non-conformiſts from inhabiting corporations," (17 Car. II. c. 2.) received the royal aſſent. Some few took the oath required by this act; but the great body of non-conformiſt miniſters refuſed it; and preferred going to baniſhment. In the year 1668, a comprehenſion (which ſee) was projected; but the ſcheme was defeated by the court-biſhops and the friends of lord Clarendon; and the perſecution was renewed. And in April 1670, the conventicle act was revived, with ſome additional clauſes. (Stat. 22 Car. II. c. 1.) On this act great numbers were proſecuted, and many induſtrious families reduced to poverty. Many miniſters were confined in gaols and cloſe priſons; and warrants were iſſued againſt them and their hearers, by which great ſums of money were levied. In 1672, a new declaration of indulgence was iſſued, which was ſoon recalled. But this mode of obtaining relief, by the exerciſe of the diſpenſing power, was very far from being ſatisfactory to the non-conformiſts. (See DISPENSATION *of the king.*) The teſt-act was paſſed in 1673. (See TEST.) In 1680, although a bill for a comprehenſion, entitled "An act for uniting his Majeſty's proteſtant ſubjects," was committed, it did not paſs the houſe, being changed for another, entitled "An act to exempt his Majeſty's proteſtant ſubjects, diſſenting from the church of England, from the penalties impoſed upon the papiſts by the act of the 35th Eliz." by which act non-conformiſts were adjudged to perpetual impriſonment, or obliged to abjure (that is) depart the realm, never to return. This terrible law had lain dormant for almoſt 80 years, but was now revived, and threatened to be put in execution by the tories. The repeal paſſed the houſe of commons with a high hand, but went heavily through the houſe of lords; but when it ſhould have been offered to the king for the royal aſſent, at the cloſe of the ſeſſion, it was miſſing, and never heard of more, the clerk of the crown having withdrawn it from the table, by the king's particular order. However, the morning before the houſe was prorogued, (Jan. 10.) two votes were paſſed of an extraordinary nature. "1. Reſolved, *nemine contradicente*, that it is the opinion of this houſe, that the acts of parliament, made in the reigns of queen Elizabeth and king James, againſt popiſh recuſants, ought not to be extended againſt proteſtant diſſenters. 2. Reſolved, that it is the opinion of this houſe, that the proſecution of proteſtant diſſenters upon the penal laws, is, at this time, grievous to the ſubject, a weakening the proteſtant intereſt, an encouragement to popery, and dangerous to the peace of the kingdom." While the parliament was endeavouring to relieve the diſſenters, many of the biſhops and clergy of the church of England were pleaſed to ſee the court inclined to proſecute the non-conformiſts; and in the year 1681. a perſecution of the diſſenters was revived by order of the king and court. After the acceſſion of James II. they were treated with great ſeverity, and had few intervals of reſt, unleſs by the diſpenſing power of the king, which they diſapproved, and the benefit of which they knew was intended for the papiſts, and not for them. But though the diſſenters ſuffered much, their number was rather augmented than diminiſhed; which ſome of their advocates have attributed to their firmneſs and conſtancy in a long courſe of trial; to their doctrine and manner of preaching; to the ſeverity of their morals; to the careful and ſtrict education of their children; to a concern for a ſucceſſion of able and learned miniſters, for which purpoſe they encouraged private academies in ſeveral parts of the kingdom; to the perſecuting zeal of the high-church party; and to the ſpirit and principles of toryiſm, which began to appear ruinous to the nation. At length the act of toleration relieved them from oppreſſion. During a courſe of ſuffering, as unmerited as it was ſevere, they were led to examine the principles of their diſſent; and the more they examined them, the more they were led to approve them, and the more firm and zealous they were in maintaining them.

Diſſenters may be led, by the brief ſurvey which we have enabled them to take of the perſecuted and diſtreſſed condition of their anceſtors, to congratulate themſelves on account of the happier circumſtances in which their lot is caſt; to maintain their ſteady attachment to a government that protects them; and to wait with patience for the arrival of that period, in which all remaining diſabilities will be removed, and the legiſlature ſhall render them capable, in conſiſtency with their avowed principles, of occupying thoſe poſts of honourable ſervice and emolument, from which they are now excluded. Their advocates allege, that whilſt they ſeparate from the eſtabliſhed church with ſome degree of reluctance, and whilſt it muſt be their wiſh to unite with the enlightened and liberal members of this church in the profeſſion of their faith, and the exerciſe of their worſhip, they are conſtrained to diſſent, not from capriciouſneſs and perverſeneſs of temper, but from the conviction of their minds, and from a conſcientious regard to what they conceive to be truth and duty. Diſſenters are not men of ſo peculiar a turn of mind, as to love ſuffering and reproach, or to deſpiſe the dignities, preferments, and lucrative poſts, which are ſhared among their fellow-ſubjects; could they with a good conſcience partake of them, as they incline to think they have a natural right to do. It has been ſaid, indeed, by a learned judge already cited, "that many diſſenters divide from the church upon matters of indifference, or, in other words, upon no reaſon at all." Allowing them to be perfectly indifferent, it has been ſaid, that the autho-

rity by which they are enjoined and made neceſſary to the inſtitutions of Chriſt, and to a participation of Chriſtian ordinances, may be reaſonably called in queſtion. The 20th article of the church of England aſſerts, indeed, "that the church hath power to decree rites and ceremonies, and hath authority in matters of faith." If the church hath really this authority and power, then all objections urged by diſſenters againſt particular articles of faith, or modes of profeſſion and worſhip, muſt be vain and impertinent; becauſe the church, ſuppoſed to poſſeſs this authority, ought to be reverently obeyed. But this authority, claimed on behalf of the church, is controverted by the diſſenters. They aſſert, that Jeſus Chriſt alone hath this authority; that he hath expreſsly commanded that no power of this kind ſhall ever be claimed, or ever be yielded, by any of his followers; that no power can make that neceſſary which he hath not made neceſſary; and that what is indifferent in its own *nature*, ought to be left indifferent in *practice*, and ſhould not be bound upon Chriſt's ſubjects either by civil or eccleſiaſtical laws: neither of which can, in this caſe, be of any validity, as being both alike of human origin. That "all things ſhould be done decently and in order" (1 Cor. xiv. 20.) they admit; but they think there is a manifeſt difference between circumſtances of natural decency and order, which are neceſſary to be agreed upon and obſerved, in order to the performance of any divine worſhip at all: and ſuch rites and ceremonies, ſuch additions to divine inſtitutions, as are not at all neceſſary, in the reaſon of the thing, or by any law of Chriſt; but only enjoined by a human, that is, in this caſe, an incompetent authority. Beſides, "a power in the church to decree rites and ceremonies, and authority in matters of faith," is a principle ſo indefinite, and ſo extenſive in its influence, that under the ſhadow of it, have grown up all the enormous innovations and ſuperſtitions of the church of Rome. But it has been ſaid, that if the church of England claims and exerciſes this power, and obliges all its miniſters to ſubſcribe to articles of faith, which it hath authoritatively decreed, and to uſe in religious worſhip ceremonies and rites, which it hath authoritatively enjoined; hath not the church of France, the church of Spain, the church of Rome the ſame authority and power? This is not an excluſive privilege pertaining to one church. If it be allowed that the church of Rome hath this prerogative, ſuch a claim, it has been ſaid, will overthrow the reformation itſelf, and ſubvert the very foundation of the church which we wiſh to eſtabliſh. It may be ſaid, however, that our church hath expreſsly guarded againſt any ſuch abuſe of the power it claims, by adding in the 20th article: "Yet is it not lawful for the church to ordain any thing that is contrary to God's word written; neither may it ſo expound one place of Scripture that it be repugnant to another." But of this repugnance and contrariety, the church, and not every private perſon, is the only proper judge: for if every private perſon hath authority to judge of the church's deciſions, and to reject them if they appear to him repugnant to Scripture, then the church's authority, in points of faith, comes to juſt nothing at all. It is an authority to decree, where none are bound to ſubmit; that is, an authority over nobody, and authority to do nothing. But if this authority be conceded to the church, it will be ſaid by ſome, that it is inconſiſtent with the natural right which every man has to judge for himſelf, and make profeſſion of that religion which he apprehends to be moſt agreeable to truth, and the ſacred writings, which are the only authoritative rule of his faith or practice, as far as it does not affect the peace and ſafety of the government under which he lives; without being determined by the prejudices of education, the laws of the civil magiſtrate, or the decrees of councils, churches, or ſynods. It will be inquired, however, where does the church pretend to be the only proper judge, or where diſallow private Chriſtians to judge for themſelves in theſe matters? To which it will be replied, the authority it claims is of this kind; it has expreſsly decreed 39 articles of faith for the purpoſe "of taking away difference of opinion, and to eſtabliſh an agreement in true religion." (See Pref. to 39 articles.) Beſides, it is alleged, that in the 34th article private judgment is forbidden to oppoſe the common order of the church, and the authority of the magiſtrate; and when it preſumes to do ſo, it is to be cenſured and puniſhed. Moreover, ſome have inquired who are the perſons that are inveſted with this authority and power? In other words, who are the church? This power to order the manner of God's worſhip, and to ſettle articles of faith, it has been ſaid, is not at all lodged in the biſhops and clergy, who are uſually denominated our ſpiritual paſtors and guides, but entirely in the king and parliament of theſe realms, under whoſe direction and controul the clergy are to act. Accordingly the diſſenters allege, that the church of England is a parliamentary church: not properly an ally, but a mere creature of the ſtate; depending entirely upon the acts and authority of parliament for its very eſſence and frame. The qualifications of its miniſters, their power to officiate, the manner in which they are to adminiſter the ſacraments, are all limited and preſcribed by authority of parliament, and this authority, which at firſt made, can alone alter and new make it; can aboliſh, or add to its articles or rites according to its pleaſure, even though the whole body of biſhops and clergy ever ſo much diſlike or proteſt earneſtly againſt it. The diſſenters farther inquire, how the civil magiſtrate has acquired this authority in the Chriſtian church? Who gave him this power to decree rites in Chriſtian worſhip, which Chriſt never decreed, and to make articles of faith, which Chriſt never made? Neither Chriſt, nor the apoſtles, as they ſay, ever gave him this authority; and therefore they wiſh to know whence it is derived? The ſubjection to higher powers, and obedience to magiſtrates, which the Scriptures enjoin on Chriſtians, relates, as they conceive, only to civil, not at all to religious matters; becauſe the magiſtrate at that time was every where pagan. So far is Chriſtianity from enjoining, that it actually forbids obedience to civil governors in things of a religious nature. It commands us to "call no man upon earth father or maſter," (Matt. xxiii. 8, 9.) *i. e.* to acknowledge no authority or juriſdiction of any in matters of religion, but to remember that "one only is our maſter" and lawgiver, even Chriſt; and that all Chriſtians are brethren, having no dominion over one another. (Matt. xx. 25.) Chriſt, the only authorized and ſovereign legiſlator of the Chriſtian church, directs his followers "to render unto Cæſar the things that are Cæſar's, and unto God, the things which are God's."

The apoſtles, who certainly, if any perſons, might have pretended to authority in matters of faith, declared, that they "had no dominion over the faith" of Chriſtians (2 Cor. i. 4.) They appealed to reaſon and conſcience, and referred the final deciſion to every man's own private judgment; "we ſpeak as unto wiſe men; judge ye what we ſay." (3 Cor. x. 15.) The Bereans are commended for "ſearching the ſcriptures" of the O.T. "daily," to ſee, "whether the things" which the apoſtles declared to them "were ſo" as they reported. And it is the duty of every Chriſtian to endeavour, for himſelf, to underſtand the ſacred oracles, as well as he is able, in the uſe of all the means and helps which divine Providence puts into his power; and thus ſhould every man "be fully perſuaded in his own mind." We believe many things upon "human authority;" meaning by authority

rity "teſtimony;" but there is a manifeſt difference between human teſtimony as to matters of fact; and human authority, as to matters of opinion, and principles of truth. The former may be, and often is, a rational ground of belief; the latter is believing upon no evidence, and is a renunciation of reaſon. The authority or teſtimony of the apoſtles, and firſt teachers of Chriſtianity, was accompanied with divine credentials; and this rendered it a ſufficient foundation for the belief, both of the facts and doctrines they revealed. And, indeed, human teſtimony, under the influence of inſpiration, and ſupported by miraculous interpoſition, is *always* a juſt ground of our belief of religious truth, as well as facts; but the authoritative decrees and injunctions of fallible, uninſpired men, *never*. The former claim an abſolute regard, as being a proof and evidence of a divine miſſion; the latter are no evidences of religious truth, or ground of belief of it at all, and therefore deſerve no regard. Should it be alleged, that other men's underſtandings are more penetrating and judicious than ours; or, that great numbers, eſpecially of perſons venerable for their age as well as for their piety and learning, are more likely to be in the right than a few individuals; and that, therefore, it will be *ſafer* to be guided by their judgments than by our own. To this argument it is replied; that a man's own underſtanding, be it more or leſs judicious, is the only faculty which God hath given him to diſtinguiſh truth from error; and as every man is accountable for the uſe of his own underſtanding, not for that of other men's; conſequently, his ſafety conſiſts not in giving up his own to the direction and controul of others, but in uſing it himſelf to the beſt advantage. And ſhould he, in the careful and conſcientious uſe of it, err; that error will never be imputed to him as a crime; whereas, if he follow the judgment of other men, though ever ſo wiſe and learned, contrary to his own ſenſe of things, he may, perchance, *profeſs* what is *right*, but he *does* what is *wrong*; and is highly criminal in the ſight of God. For, the profeſſion of any doctrine ſhould always follow conviction of the truth of it; at leaſt, a man muſt never profeſs what is contrary to his conviction. To embrace or profeſs any point which he does not believe to be true, in compliment to human authority, is exalting *human* into the place of *divine* authority; and ſaying in one word, "that it is better to obey man than God." It has been further obſerved, that ſubmitting to the deciſions of human authority in matters of faith is ſometimes prejudicial to, and ſubverſive of, true religion, where it does not iſſue in downright hypocriſy. For as, on the one hand, by the exerciſe of our rational faculties in ſearching after truth, we are not only likely to arrive at it, but to improve in the love of it, in candour, docility, and openneſs to conviction; and are diſpoſed to ſubmit to its influence; ſo, on the contrary, in proportion as we reſign ourſelves to the conduct of human authority, truth loſes its charms, and its influence over us; and we become blind to its cleareſt evidences, and brighteſt characters, and are thus prepared to be led into the moſt abſurd ſuperſtitions, and vileſt corruptions of religion. (See HERESY.) Should it be ſaid that no man is at liberty to declare or profeſs any ſentiments different from thoſe by law eſtabliſhed; this maxim, it may be replied, will vindicate the exerciſe of human authority in ſupport of every eſtabliſhment that ever was or will be: Mohammediſm at Conſtantinople; popery at Rome; epiſcopacy in England; preſbyterianiſm at Geneva, or in Scotland. The ſame principle, purſued to its conſequences, would have precluded the reformation from popery, and would even have ſtifled in its birth our holy religion itſelf.

By ſuch reaſoning diſſenters have vindicated the right of private judgment in the province of religion, and their deviation, with regard to articles of faith and forms of worſhip, from the national eſtabliſhment. The church, they ſay, is the kingdom of Chriſt, "a kingdom not of this world;" and he is the *ſole* lawgiver, ſovereign, and judge, in all matters of religion; and whilſt "they ſtand faſt in the liberty with which he has made them free," they think themſelves exempt from the charge of *ſchiſm*, (which ſee.) in departing peaceably from the communion of the eſtabliſhed church. (See CHURCH.) If we inquire, they ſay, after the conſtitution of the church of Chriſt, we muſt look for it only in the *Bible*; according to the maxim of the excellent Chillingworth; "the bible only is the religion of proteſtants; but the conſtitution of the church of England is found in the ſtatute-book, in the canons, and common-prayer book, and in the codes of the Engliſh law."

Differing from one another, as well as from the articles of the eſtabliſhed church, in a variety of ſpeculative opinions, and alſo from eſtabliſhed forms and ceremonies, the diſſenters allege that theſe were drawn up when the kingdom was juſt emerging out of popiſh darkneſs; and that in drawing them up, eſpecial regard was had to the *then* weakneſs of the people, who could not all at once be entirely brought off from the old ceremonies and forms; and that there are ſeveral parts of our liturgy, and eccleſiaſtical conſtitution, which many, even of our biſhops and clergy, have wiſhed to ſee altered; but they chiefly object to the *impoſition* of rites and practices that are mutable and indifferent, and of doctrines, concerning which the wiſeſt and beſt men have diſagreed, and may continue to diſagree without injury or danger, as long as they preſerve the unity of the faith in the bond of peace and mutual forbearance. They object to *ſponſors* in baptiſm, *confirmation*, the *abſolution* of the ſick and dying, kneeling at the *ſacrament* and the adminiſtration of it as a teſt, the preſcribed and indiſpenſable uſe of certain *habits*, the office for burial of the dead, bowing at the name of Jeſus, ſubſcription to articles of faith, compoſed by fallible men, the damnatory clauſes of the Athanaſian creed, the nature and mode of epiſcopal ordination, the withholding from Chriſtian laity the right of chuſing their own miniſters, the various ranks and powers ſubſiſting among the clergy, &c. &c. &c. Diſſenters object, and more particularly, to the impoſition of articles of faith, and ceremonies of worſhip, which they conceive to be unauthoriſed by the ſcripture, and inconſiſtent with their notion of its ſufficiency, and with the right of private judgment.

As to the political principles and conduct of the diſſenters, it will be ſufficient, as they apprehend, to refer to the truth of hiſtory, impartially and candidly contemplated, and to the unequivocal teſtimony of their advocates and even of many of their adverſaries, ancient and modern. It has been ſaid, indeed, that the diſſenters hold principles unfriendly to ſociety, and to civil government; principles, which, in the extreme, have produced the moſt fatal effects, both at home and abroad; but this has been chiefly ſaid by perſons who have confounded their principles, in their nature and tendency, with thoſe, which, being carried to an extreme by the anabaptiſts in Germany, and the high-monarchy men in England, in the 17th century, produced very extravagant conſequences. Whilſt, in the opinion of proteſtant diſſenters, the magiſtrate ſhould not expect, much leſs exact, obedience or ſubmiſſion in matters purely religious, and that in things pertaining to conſcience, it is the duty of the ſubject to act upon the principle of the apoſtles and primitive Chriſtians; that is, to "obey God rather than man:" they are ſo far from ſetting up the ſuppoſed intereſts of religion againſt lawful magiſtracy, or the peace and good order

order of ſociety, that they allow of the exemption of none from the authority of the civil magiſtrate; holding all to be equally under his juriſdiction; and that no plea of ſacred character, or of religion and conſcience, is to be admitted in bar to his procedure, in matters of a criminal, or merely civil nature. And as, in their opinion, it is his duty to *protect* all *good ſubjects* in the profeſſion of their religious principles; ſo, without any regard to their religious principles or profeſſions, he is to *puniſh* all *offenders* againſt the *peace* of ſociety. No diſſenter on earth is now ſo abſurd as to hold, that "dominion is founded in grace," and that "the ſaints muſt rule the world;" or any principles which have the leaſt tendency and aſpect towards ſuch a concluſion. On the contrary, they all aſſert, that religion is ſo far from veſting in its profeſſors a title to *dominion*, that it is no exemption from *civil ſubjection*. It is in matters of conſcience only, they apprehend, they are alone accountable to God: and that not ſo as to excuſe thereby any criminal overt acts, inconſiſtent with the peace of ſociety: *theſe* the magiſtrate muſt puniſh, from whatever principle they proceed, from any or none, and whatever plea of that ſort is offered in their favour. The diſſenters zealouſly maintain, in conformity with reaſon and ſcripture, that "Chriſt's kingdom is not of this world," and doth not at all interfere with the office of the magiſtrate; who, in their opinion, is ſupreme over all perſons within his dominions, of whatever religion, of any or none. In a word, their principles, with reſpect both to church-authority and to civil government, are preciſely the ſame which biſhop Hoadly advanced, and ſupported by ſound argument; doing thereby ſuch ſervice to the cauſe of true proteſtantiſm, and of the royal ſucceſſion in the houſe of Hanover, as will always be remembered with gratitude by the true friends of that auguſt family and of the liberties of their country. It has been affirmed by thoſe who beſt knew their principles, that there are no better ſubjects, and no better friends to the conſtitution of their country as a limited monarchy, defined and improved by the glorious revolution, than the proteſtant diſſenters; they pray for the continuance of the proteſtant ſucceſſion in the preſent illuſtrious family, and for the *ſalus regis et populi*, in the words, and with the fervour, with which father Paul prayed for the republic of Venice in his dying moments; "ESTO PERPETUA!" How their anceſtors acted in the period preceding the revolution, appears in the abſtract of their hiſtory which we have already given. Of their firm and zealous attachment to the family on the throne, they have given unequivocal proofs. When the kingdom, about the middle of the laſt century, was aſſailed by the adherents of another claimant to the crown; when the loyalty of many of thoſe who were near the perſon of the king was ſuſpected, and when terror had palſied even more than corruption had ſeduced; there was not *one* man, not a *ſingle individual* of their ſociety, who joined the enemies of his majeſty's houſe: at that time, the diſſenters, regardleſs of the dreadful penalties of the law, and anxious for their country alone, eagerly took arms; and as ſoon as the danger was paſſed by, they were compelled to ſolicit the protection of that general *mercy* which was extended to the very rebels againſt whom they fought, and to ſhelter themſelves under that *act of grace*, which was granted to the very *traitors* from whoſe arms they had defended the crown and life of their ſovereign. Amongſt thoſe who have borne honourable teſtimony to the principles and character of the diſſenters as members of the civil community, we may mention Dr. Secker, archbiſhop of Canterbury, who, in his "Letter to Mr. Walpole concerning biſhops in America," ſays, "the diſſenters are ſincere well wiſhers to the civil part of our preſent happy eſtabliſhment; and they are to be eſteemed and loved for it." The teſtimony of this prelate is the more important, as he was not only born of diſſenting parents, but received his education, together with the late excellent biſhop Butler, in one of their academies, under a tutor, whoſe great learning and abilities would have been no little honour to either of our univerſities. Lord North, in the courſe of the debate on a motion for the repeal of the teſt laws, whilſt he was pronouncing a panegyric on the conſtitution of the church, liberally declared, that when he profeſſed an attachment to the principles on which thoſe laws reſted, he did not mean to throw any reflection on the opinions of thoſe who conſcientiouſly differed from his ſentiments. He deprecated the idea, that he ſhould be thought to treat the diſſenters as men, who deſerved diſlike or puniſhment. He knew their virtue, their morality, their learning. The right honourable Mr. Charles Fox, referring in the ſame debate to the teſtimony borne in favour of the diſſenters by lord North, ſaid, he had ſpoken liberally and handſomely of the diſſenters. Why? becauſe he felt the propriety and the juſtice of ſuch a teſtimony. He knew that they had been ſteady in their attachment to government; that their religious opinions were favourable to civil liberty; and that the true principles of the conſtitution had been remembered, and aſſerted by them, at times, when they were forgotten, perhaps betrayed, by the church. Such had been the character of the diſſenters; and he farther maintained, that their political opinions were not now different from what they had been formerly. Pierce's Vindiciæ, &c. Neal's Hiſt. DISSENTIS. See DISENTIS.

DISSEPIMENTUM, a partition, in *Botany*, ſerves to divide the internal part of a fruit into two or more cells. The partitions of a capſule ſometimes originate from the centre of its valves, as in Juſſieu's natural order of *Ericæ*, or from the inflexed margins of thoſe valves as in his *Rhododendra*. Hence he has lately ſeparated from the former order the *Erica Dabeoci* Sm. Fl. Brit. 420. Engl. Bot. t. 35, and referred it to *Menzieſia*, a genus founded by Dr. Smith upon that very circumſtance. It appears however that ſome ſuppoſed *Ericæ* have the ſame ſtructure, though none of the *Rhododendra* have a partition from the centre of their valves. Some plants have partitions ſpringing from the central pillar or *columella*. Pods, *Siliquæ*, have moſtly a longitudinal membranous partition, dividing them into two cells, with a thick edge to which the valves are originally attached, as in the Sattin-flower, *Lunaria*, the various kinds of Stock, *Cheiranthus*, &c.

DISSIDENTS, in a general ſenſe, denote thoſe who differ from the eſtabliſhed religion of the country in which they live: but, in its more appropriate meaning, the denomination is applied in Poland to thoſe of the Lutheran, Calviniſtic, and Greek profeſſion. The hiſtory of this party, as it is ſketched by the Poliſh hiſtorians, is detailed by Mr. Coxe in his hiſtory of Poland. (Travels, vol. i.) The reformation was introduced in the reign of Sigiſmond I. who aſcended the throne in the year 1506, and who perſecuted its followers: but their number, however, increaſing, his ſon Sigiſmond Auguſtus, who ſucceeded his father in 1548, not only indulged them in the liberal exerciſe of their worſhip, but admitted them, together with the Greeks, and all other ſects then ſubſiſting in Poland, to a ſeat in the diet, and to all the honours and privileges hitherto confided to the catholics. Theſe maxims of unlimited toleration were generally adopted by the nation, and the members of the diet, which aſſembled upon the deceaſe of Sigiſmond Auguſtus, being of different perſuaſions,

perſuaſions, determined on a reciprocal indulgence of their reſpective tenets. To avoid invidious diſtinctions, they called themſelves indiſcriminately "diſſidents in religion," a phraſe intimating, not, according to our notions, ſeparatiſts from an eſtabliſhed church, but perſons holding different opinions in religious matters. It was at the ſame time enacted, that this difference of religious ſentiments ſhould create no difference in civil rights; and accordingly in the *Pacta conventa* formed by the diet, a clauſe was inſerted as part of the coronation oath: "I will keep peace among the diſſidents." Henry, who objected to this univerſal toleration, withheld his conſent, till one of the Poliſh envoys exclaimed, "Unleſs you confirm this article, you cannot be king of Poland:" he accordingly took an oath to obſerve this clauſe, before he was permitted to aſcend the throne. In proceſs of time, the Roman Catholics, having acquired a conſiderable aſcendency, ventured to apply the appellation of diſſidents to all thoſe who diſſented from the catholic religion. This reſtriction was at firſt attended with no encroachments on the privileges of the other ſects; and the term diſſidents was not regarded in an obnoxious light. The diſſidents indeed ſtill continued in ſuch unqueſtioned poſſeſſion of all rights, civil and religious, that, when it was agreed by both catholics and proteſtants to perſecute the Arians, it was thought previouſly neceſſary to expel them from the body of diſſidents. In conſequence of this excluſion, the Arians, in the reign of John Caſimir, were firſt rendered incapable of being elected nuntios, afterwards deprived of their places of worſhip, and finally baniſhed. This perſecution, inadvertently aſſented to by the Proteſtants and Greeks, was a prelude to their ſufferings: for, as the Catholic party predominated, the term diſſidents, at firſt confined to perſons profeſſing the Proteſtant religion, *viz.* the Lutherans and Calviniſts (other Proteſtant ſects, ſuch as the Mennonites, Anabaptiſts, Quakers, and Arians, not being included among the diſſidents,) and that of the Greek church, became of a leſs inoffenſive import, and conveyed an idea of non-conformity The ſectaries, accordingly, who were ſtill diſtinguiſhed by the appellation of diſſidents, perceiving the intention of the Catholics to undermine their privileges, obtained a declaration, that they ſhould not be blended with, and be obnoxious to the penal laws enacted againſt the Arians. But theſe promiſes were inſenſibly eluded; their privileges were gradually diminiſhed, in the courſe of a few years they were ſubjected to a variety of diſqualifications, and, at length, in 1733, formally incapacitated from ſitting in the diet. A law of Ladiſlaus II. againſt heretics, as well as the penalties againſt the Arians, were revived, and occaſionally extended to the diſſidents. Theſe continual perſecutions greatly diminiſhed their number, and rendered their remonſtrances ineffectual: the catholics, who took the lead in the diet, even declared it high treaſon to ſeek the reſtoration of their immunities by the interceſſion of foreign powers, in direct contradiction to the treaty of Oliva, in which it was ſtipulated, that the rights of the diſſidents ſhould be maintained in their full latitude.

Such was the ſituation of the diſſidents at the acceſſion of Staniſlaus Auguſtus, who, though ſtrongly inclined to toleration, was obliged to concur with the general ſenſe of the diet, and confirm the laws which had been promulgated againſt them. The diſſidents applied to the courts of London, Peterſburg, Berlin, and Copenhagen, as the mediating powers in the treaty of Oliva, who warmly ſupported their cauſe, and preſented memorials to the diet, demanding a reſtoration of their religious eſtabliſhments, and of all the privileges ſecured to them by that treaty. The diet of 1766, however, was not of a temper to accede to theſe propoſals. The enemies of toleration contended that the privileges were obſolete, having been repeatedly aboliſhed in various diets, and that the diſſidents had no well-founded claim either to the reſtitution of their civil immunities, or to the toleration of their worſhip: the biſhop of Cracow, the moſt bigotted of the catholics, even propoſed a law againſt their catholic abettors. Violent altercations aroſe in the aſſembly; and the members ſeparated in great diſorder. On a ſubſequent day, the violence of party was renewed, and the acts againſt the diſſidents confirmed. But to conciliate the mediating powers, the bench of biſhops, by command of the diet, drew up nine articles in favour of the diſſidents, relative to the free exerciſe of their worſhip. Theſe acceſſions not being deemed ſufficiently favourable, while the exceptionable laws were unrepealed, the empreſs of Ruſſia remonſtrated againſt the proceedings of the diet, and the diſſidents began to form confederacies in different parts of the kingdom. They were joined by many diſcontented catholics, and aſſiſted by a large body of Ruſſian troops, who entered Thorn, where the firſt and principal confederacy took its riſe. All the mediating powers, Great Britain, Denmark, Pruſſia, and Sweden, teſtified their approbation of theſe confederacies, which gradually comprehended political grievances, and which were ſtrengthened by other confederacies among the catholic nobles, who affected to be advocates for toleration, and declared their intentions of ſupporting the cauſe of the diſſidents. The coalition of this catholic confederacy with that of the diſſidents, ſoon afterwards took place in the palace of prince Radzivil at Warſaw. The king convoked a diet for the purpoſe of reconciling the oppoſite parties, but it failed in producing the intended effect. This diet, in a very intimidated and tumultuous ſtate, appointed a grand committee, to adjuſt, in conjunction with the mediating powers, the affairs of the diſſidents, and then broke up. This committee propoſed to repeal all the laws enacted againſt the diſſidents, and to reſtore their ancient privileges; and their pacific reſolutions were ratified at an extraordinary diet, convened in the beginning of the year 1768. In conſequence of theſe meaſures, Poland enjoyed for a moment an univerſal tranquillity; but it was that ſullen calm, which precedes a tempeſt, and announces the approach of violent commotions. The diet had not been long diſſolved, before the indulgences granted to the diſſidents excited general diſſatisfaction among the Roman catholics, who formed ſeveral confederacies in defence of the ſacred catholic faith. From this time, Poland became a ſcene of bloodſhed and devaſtation; and hoſtilities were protracted from the diſſolution of the diet in 1768 to the diviſion of Poland in 1772. At the laſt meeting of the delegates, who were appointed to adjuſt the terms of the diſmemberment in 1773, the pretenſions of the diſſidents were finally ſettled between the republic and the mediating powers. The catholic party violently oppoſing the reſtoration of their ancient privileges, by the conſent of the foreign courts, they continued excluded from the diet, the ſenate, and the permanent council. In return, the diſſidents enjoyed the free exerciſe of their religion, were permitted to have churches without bells, ſchools, and ſeminaries, were capable of ſitting in the inferior courts of juſtice, and in the tribunal appointed to try appeals in matters of religion, three of their communion were admitted as aſſeſſors. In conſequence of this toleration, the diſſidents conſtructed churches in different parts of the kingdom; and one built upon this occaſion by the Lutherans at Warſaw, has the following inſcription:

"Hæc

" Has ædes Deo J. O. ſacras
Cœtus Varſovienſis in Auguſt. Confeſs. ex
Conſenſu Staniſlai Auguſti Regis et Reipublicæ
Struere Cœpit, Aprilis 24, 1777."

See POLAND.

DISSIMILAR, in *Anatomy*. Authors divide the parts of the body into ſimilar, and diſſimilar.

Diſſimilar parts, by ſome called alſo compound, and organical parts, are ſuch as may be divided into various parts, of different ſtructure, &c. Thus the hand is diviſible into veins, muſcles, bones, &c. whoſe ſubdiviſions are neither of the ſame nature nor denomination.

DISSIMILAR *Leaves*, denote the two firſt leaves of any plant at its firſt ſhooting out of the ground.

They are thus called, becauſe they uſually are of a different form from the common leaves of a grown plant.

Theſe Dr. Grew obſerves to be nothing but the very lobes of the ſeed thus expanded, and thus advanced.

Their uſe is for the protection of the plume; which being young and tender, is thus guarded on each ſide, and has alſo ſome rain and dew gradually conveyed down to it by this means. See PLUME.

DISSIMILITUDE, in *Geometry*, &c. See SIMILITUDE.

DISSIMILITUDE, or *Diſſimili*, in *Rhetoric*, &c. is a diſagreement of things in quality, and furniſhes an argument, wherein, from diſſimilar, or unlike things, other diſſimilars are deduced.

Thus Cicero, " Si barbarorum eſt in diem vivere; noſtra conſilia ſempiternum tempus ſpectare debent." Thus alſo Cicero (in Piſon. c. 14, &c.) ſhews the preference of his own exile to Piſo's government of Macedonia, by the difference between their conduct, and the people's eſteem of them. Catullus furniſhes a very beautiful argument from diſſimilitude.

" Soles occidere & redire poſſunt,
Nobis cum ſemel occidit brevis lux,
Nox eſt perpetua una dormienda."
